About this document

This document supports z/OS® (5650-ZOS). This document contains information about using Enterprise Identity Mapping (EIM). EIM is an architecture that serves as a security technology to make it easier to manage users in a cross-platform environment. For a detailed introduction of EIM, see Chapter 1, “Enterprise Identity Mapping (EIM),” on page 3.

Who should use this document

EIM requires a Lightweight Directory Access Protocol (LDAP) server because EIM data is stored in LDAP. (For information about LDAP requirements, see “Planning considerations for an EIM domain controller” on page 41.) EIM optionally requires RACF® or an equivalent external security manager.

Those who might find this document helpful include the following:
• EIM administrators who plan, install, configure, customize, administer, or use EIM
• RACF administrators who issue commands in support of EIM
• Application programmers
• LDAP administrators who install, configure, or administer LDAP in support of EIM
(See “Team members” on page 33 for a complete list of team members.)

This document assumes that you are familiar with the following concepts and protocols:
• LDAP
• z/OS UNIX System Services shell
• C/C++ programming languages

How to use this document

For a detailed introduction of EIM, see Chapter 1, “Enterprise Identity Mapping (EIM),” on page 3.

Where to find more information

Where necessary, this book refers to information in other books. For complete titles and order numbers for all elements of z/OS, see z/OS Information Roadmap.

Other sources of information

IBM provides customer-accessible discussion areas where EIM and RACF may be discussed by customer and IBM participants. Other information is also available through the Internet.

Internet sources

EIM is a cross-platform infrastructure that is available on the following platforms:
• iSeries
• pSeries
• xSeries
• zSeries
The following resources are available through the Internet to provide additional information about EIM and other security-related topics:

- z/OS Internet library (www.ibm.com/servers/resourcelink/svc00100.nsf/pages/zosInternetLibrary)
- IBM Redbooks (www.ibm.com/redbooks)
- Enterprise security (www.ibm.com/systems/z/solutions/enterprise-security.html)
- RACF home page (www.ibm.com/systems/z/os/zos/features/racf)
- RACF download page (www.ibm.com/systems/z/os/zos/features/racf/goodies.html)
How to send your comments to IBM

We invite you to submit comments about the z/OS product documentation. Your valuable feedback helps to ensure accurate and high-quality information.

**Important:** If your comment regards a technical question or problem, see instead “If you have a technical problem” on page xvii.

Submit your feedback by using the appropriate method for your type of comment or question:

**Feedback on z/OS function**
If your comment or question is about z/OS itself, submit a request through the IBM RFE Community (www.ibm.com/developerworks/rfe/).

**Feedback on IBM® Knowledge Center function**
If your comment or question is about the IBM Knowledge Center functionality, for example search capabilities or how to arrange the browser view, send a detailed email to IBM Knowledge Center Support at ibmkc@us.ibm.com.

**Feedback on the z/OS product documentation and content**
If your comment is about the information that is provided in the z/OS product documentation library, send a detailed email to mhvrcfs@us.ibm.com. We welcome any feedback that you have, including comments on the clarity, accuracy, or completeness of the information.

To help us better process your submission, include the following information:

- Your name, company/university/institution name, and email address
- The following deliverable title and order number: z/OS Integrated Security Services EIM Guide and Reference, SA23-2297-30
- The section title of the specific information to which your comment relates
- The text of your comment.

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute the comments in any way appropriate without incurring any obligation to you.

IBM or any other organizations use the personal information that you supply to contact you only about the issues that you submit.

**If you have a technical problem**
If you have a technical problem or question, do not use the feedback methods that are provided for sending documentation comments. Instead, take one or more of the following actions:

- Go to the IBM Support Portal (support.ibm.com).
- Contact your IBM service representative.
- Call IBM technical support.
Summary of changes

z/OS Version 2 Release 1 summary of changes

See the Version 2 Release 1 (V2R1) versions of the following publications for all enhancements related to z/OS V2R1:

- z/OS Migration
- z/OS Planning for Installation
- z/OS Summary of Message and Interface Changes
- z/OS Introduction and Release Guide
Part 1. EIM concepts and use
Chapter 1. Enterprise Identity Mapping (EIM)

Today’s network environments are made up of a complex group of systems and applications, resulting in the need to manage multiple user registries. Dealing with multiple user registries quickly grows into a large administrative problem that affects users, administrators, and application developers. Consequently, many companies are struggling to securely manage authentication and authorization for systems and applications. Enterprise Identity Mapping (EIM) is an IBM eServer infrastructure technology that allows administrators and application developers to address this problem more easily and inexpensively than previously possible.

The following information describes the problems, outlines current industry approaches, and explains why the EIM approach is better.

The problem: Managing multiple user registries

Many administrators manage networks that include different systems and servers, each with a unique way of managing users through various user registries. In these complex networks, administrators are responsible for managing each user’s identities and passwords across multiple systems. Additionally, administrators often must synchronize these identities and passwords and users are burdened with remembering multiple identities and passwords and with keeping them in sync. The user and administrator overhead in this environment is excessive. Consequently, administrators often spend valuable time troubleshooting failed logon attempts and resetting forgotten passwords instead of managing the enterprise.

The problem of managing multiple user registries also affects application developers who want to provide multiple-tier or heterogeneous applications. These developers understand that customers have important business data spread across many different types of systems, with each system possessing its own user registries. Consequently, developers must create proprietary user registries and associated security semantics for their applications. Although this solves the problem for the application developer, it increases the overhead for users and administrators.

Current approaches

Several current industry approaches for solving the problem of managing multiple user registries are available, but they all provide incomplete solutions. For example, Lightweight Directory Access Protocol (LDAP) provides a distributed user registry solution. However, using LDAP (or other popular solutions such as Microsoft Passport) means that administrators must manage yet another user registry and set of security semantics or must replace existing applications that are built to use those registries.

Using this type of solution, administrators must manage multiple security mechanisms for individual resources, thereby increasing administrative overhead and potentially increasing the likelihood of security exposures. When multiple mechanisms support a single resource, the chance of changing the authority through one mechanism and forgetting to change the authority for one or more of the other mechanisms is much higher. For example, a security exposure can result when a user is appropriately denied access through one interface, but allowed access through one or more other interfaces.

After completing this work, administrators find that they have not completely solved the problem. Generally, enterprises have invested too much money in current user registries and in their associated security semantics to make using this type of solution practical. Creating another user registry and associated security semantics solves the problem for the application provider, but not the problems for users or administrators.

One other possible solution is to use a single sign-on approach. Several products are available that allow administrators to manage files that contain all of a user’s identities and passwords. However, this approach has several weaknesses:
It addresses only one of the problems that users face. Although it allows users to sign on to multiple systems by supplying one identity and password, it does not eliminate the need for the user to have passwords on other systems, or the need to manage these passwords.

It introduces a new problem by creating a security exposure because clear-text or decryptable passwords are stored in these files. Passwords should never be stored in in clear-text files or be easily accessible by anyone, including administrators.

It does not solve the problems of third-party application developers who provide heterogeneous, multiple-tier applications. They must still provide proprietary user registries for their applications.

Despite these weaknesses, some enterprises have chosen to adopt these approaches because they provide some relief for the multiple user registry problems.

The EIM approach

EIM offers a new approach to enable inexpensive solutions to easily manage multiple user registries and user identities in an enterprise. EIM is an architecture for describing the relationships between individuals or entities (like file servers and print servers) in the enterprise and the many identities that represent them within an enterprise. In addition, EIM provides a set of APIs that allow applications to ask questions about these relationships.

For example, given a person's user identity in one user registry, you can determine which user identity in another user registry represents that same person. If the user has authenticated with one user identity and you can map that user identity to the appropriate identity in another user registry, the user does not need to provide credentials for authentication again. You know who the user is and only need to know which user identity represents that user in another user registry. Therefore, EIM provides a generalized identity mapping function for the enterprise.

EIM allows one-to-many mappings (in other words, a single user with more than one user identity in a single user registry). However, the administrator does not need to have specific individual mappings for all user identities in a user registry. EIM also allows many-to-one mappings (in other words, multiple users mapped to a single user identity in a single user registry).

The ability to map between a user's identities in different user registries provides many benefits. Primarily, it means that applications may have the flexibility of using one user registry for authentication while using an entirely different user registry for authorization. For example, an administrator could map an SAP identity (or better yet, SAP could do the mapping itself) to access SAP resources.

The use of identity mapping requires that administrators do the following:

1. Create EIM identifiers that represent people or entities in their enterprise
2. Create EIM registry definitions that describe the existing user registries in their enterprise
3. Define the relationship between the user identities in those registries to the EIM identifiers that they created
4. Create policy associations

No code changes are required to existing user registries. The administrator does not need to have mappings for all identities in a user registry. EIM allows one-to-many mappings (in other words, a single user with more than one user identity in a single user registry). EIM also allows many-to-one mappings (in other words, multiple users sharing a single user identity in a single user registry, which although supported is not advised). An administrator can represent any user registry of any type in EIM.

EIM is an open architecture that administrators may use to represent identity mapping relationships for any registry. It does not require copying existing data to a new repository and trying to keep both copies synchronized. The only new data that EIM introduces is the relationship information. Administrators manage this data in an LDAP directory, which provides the flexibility of managing the data in one place and having replicas wherever the information is used. Ultimately, EIM gives enterprises and application developers the flexibility to easily work in a wider range of environments with less cost than would be possible without this support.
Chapter 2. EIM concepts

A conceptual understanding of how Enterprise Identity Mapping (EIM) works is necessary to fully understand how you can use EIM in your enterprise. Although the configuration and implementation of EIM APIs can differ among server platforms, EIM concepts are common across IBM eServer™ servers.

The following figure provides an EIM implementation example in an enterprise. Three servers act as EIM clients and contain EIM-enabled applications that request EIM data using lookup operations. The domain controller stores information about the EIM domain, which includes an EIM identifier, associations between these EIM identifiers and user identities, and EIM registry definitions.

Figure 1: Overview of an EIM implementation

Review the following information to learn more about these EIM concepts:

• “EIM domain controller” on page 6
• “EIM domain” on page 6
• “EIM identifier” on page 8
• “EIM registry definition” on page 11
• “EIM associations” on page 15
• “EIM lookup operation” on page 21
• “EIM access control” on page 26
The EIM domain controller is a Lightweight Directory Access Protocol (LDAP) server that is configured to manage at least one EIM domain. The z/OS LDAP is the IBM Tivoli Directory Server LDAP server (IBM TDS LDAP server).

An EIM domain is an LDAP directory that consists of all the EIM identifiers, EIM associations, and user registries that are defined in that domain. Systems (EIM clients) participate in the EIM domain by using the domain data for EIM lookup operations. A minimum of one EIM domain controller must exist in the enterprise.

Currently, you can configure some IBM platforms to act as an EIM domain controller. Any system that supports the EIM APIs can participate as a client in the domain. These client systems use EIM APIs to contact an EIM domain controller to perform EIM lookup operations. Refer to “EIM lookup operation” on page 21 for more information.

The location of the EIM client determines whether the EIM domain controller is a local or remote system. The domain controller is local if the EIM client is running on the same system as the domain controller. The domain controller is remote if the EIM client is running on a separate system from the domain controller.

An EIM domain is a directory within a Lightweight Directory Access Protocol (LDAP) server that contains EIM data for an enterprise. An EIM domain is the collection of all the EIM identifiers, EIM associations, and user registries that are defined in that domain. Systems (EIM clients) participate in the domain by using the domain data for EIM lookup operations.

An EIM domain is different from a user registry. A user registry defines a set of user identities known to and trusted by a particular instance of an operating system or application. A user registry also contains the information needed to authenticate the user of the identity. Additionally, a user registry often contains other attributes such as user preferences, system privileges, or personal information for that identity.

In contrast, an EIM domain refers to user identities that are defined in user registries. An EIM domain contains information about the relationship between identities in various user registries (user name, registry type, and registry instance) and the actual people or entities that these identities represent. Because EIM tracks relationship information only, there is nothing to synchronize between user registries and EIM.

The following figure shows the data that is stored within an EIM domain. This data includes EIM identifiers, EIM registry definitions, and EIM associations. EIM data defines the relationship between user identities and the people or entities that these identities represent in an enterprise.
Figure 2: EIM domain and the data that is stored within the domain

EIM data includes:

**EIM identifier**
Each EIM identifier that you create represents a person or entity (such as a print server or a file server) within an enterprise. See “EIM identifier” on page 8 for more information about this concept.

**EIM registry definition**
Each EIM registry definition that you create represents an actual user registry (and the user identity information it contains) that exists on a system within the enterprise. Once you define a specific user
registry in EIM, that user registry can participate in the EIM domain. You can create two types of registry definitions, one type refers to system user registries and the other type refers to application user registries. See “EIM registry definition” on page 11 for more information about this concept.

EIM association
Each EIM association that you create represents the relationship between an EIM identifier and an associated identity within an enterprise. You must define associations so that EIM clients can use EIM APIs to perform successful EIM lookup operations. These EIM lookup operations search an EIM domain for defined associations between EIM identifiers and user identities in recognized user registries. Associations provide the information that ties an EIM identifier to a specific user identity in a specific user registry. See “EIM lookup operation” on page 21 for more information about this concept. There are two different types of associations that you can create:

- **Identifier associations.** Identifier associations allow you to define a one-to-one relationship between user identities through an EIM identifier defined for an individual. Each EIM identifier association that you create represents a single, specific relationship between an EIM identifier and an associated user identity within an enterprise. Identifier associations provide the information that ties an EIM identifier to a specific user identity in a specific user registry and allow you to create one-to-one identity mapping for a user. Identity associations are especially useful when individuals have user identities with special authorities and other privileges that you want to specifically control by creating one-to-one mappings between their user identities.

- **Policy associations.** Policy associations allow you to define a relationship between a group of user identities in one or more user registries and an individual user identity in another user registry. Each EIM policy association that you create results in a many-to-one mapping between the source group of user identities in one user registry and a single target user identity. Typically, you create policy associations to map a group of users who all require the same level of authorization to a single user identity with that level of authorization.

Once you create your EIM identifiers, registry definitions, and associations, you can begin using EIM to more easily organize and work with user identities within your enterprise.

EIM identifier
An EIM identifier represents a person or entity in an enterprise. A typical network consists of various hardware platforms and applications and their associated user registries. Most platforms and many applications use platform-specific or application-specific user registries. These user registries contain all of the user identification information for users who work with those servers or applications.

When you create an EIM identifier and associate it with the various user identities for a person or entity, it becomes easier to build heterogeneous, multiple-tier applications (for example, a single sign-on environment). When you create an EIM identifier and associations, it also becomes easier to build and use tools that simplify the administration involved with managing every user identity that a person or entity has within the enterprise.

EIM identifier representing a person
The following figure shows an example of an EIM identifier that represents a person named John Day and his various user identities in an enterprise. In this example, the person John Day has four user identities in four different user registries, which are johnday, jsd1, JOHND, and JDay.
Figure 3: The relationship between the EIM identifier for a real person, John Day, and his various user identities.

In EIM, you can create associations that define the relationships between the John Day identifier and each of the different user identities for John Day. By creating these associations to define these relationships, you and others can write applications that use the EIM APIs to look up a needed, but unknown, user identity based on a known user identity.

**EIM identifier representing an entity**

In addition to representing users, EIM identifiers can represent entities within your enterprise as Figure 4 illustrates. For example, often the print server function in an enterprise runs on multiple systems. In the following example, there are three print servers in the enterprise running on three different systems under three different user identities of pserverID1, pserverID2, and pserverID3.
Figure 4: The relationship between the EIM identifier that represents the printer server function, and the various identities for that function.

With EIM, you can create a single identifier that represents the print server function within the entire enterprise. In this example, the EIM identifier print server function represents the actual print server function entity in the enterprise. Associations are created to define the relationships between the EIM identifier (print server function) and each of the user identities for this function (pserverID1, pserverID2, and pserverID3). These associations allow application developers to use EIM lookup operations to find a specific print server function. Application providers can then write distributed applications that manage the print server function more easily across the enterprise.

**EIM identifiers and aliasing**

You can also create aliases for EIM identifiers. Aliases can aid in locating a specific EIM identifier when performing an EIM lookup operation. For example, aliases can be useful in situations where someone's legal name is different from the name that that person is known as.

EIM identifier names must be unique within an EIM domain. Aliases can help address situations where using unique identifier names can be difficult. For example, different individuals within an enterprise can share the same name, which can be confusing if you are using proper names as EIM identifiers.

The following figure illustrates an example in which an enterprise has two users named John S. Day. The EIM administrator creates two different EIM identifiers to distinguish between them: John S Day1 and John S. Day2. However, which real John S. Day is represented by each of these identifiers is not readily apparent.
By using aliases, the EIM administrator can provide additional information about the individual for each EIM identifier. This information can also be used in an EIM lookup operation to distinguish between the users that the identifier represents. For example, the alias for John S. Day1 might be John Samuel Day and the alias for John S. Day2 might be John Steven Day.

Each EIM identifier can have multiple aliases to identify which John S. Day the EIM identifier represents. The EIM administrator might add another alias to each of the EIM identifiers for the two individuals to further distinguish between them. For example, the additional aliases might contain each user’s employee number, department number, job title, or other distinguishing attribute.

You can use the alias information to aid in locating a specific EIM identifier. For example, an application that uses EIM may specify an alias that it uses to find the appropriate EIM identifier for the application. An administrator can add this alias to an EIM identifier so that the application can use the alias rather than the unique identifier name for EIM operations. An application can specify this information when using the Get EIM Target Identities from the Identifier (eimGetTargetFromIdentifier) API to perform an EIM lookup operation to find the appropriate user identity it needs.

**EIM registry definition**

An EIM registry definition represents an actual user registry that exists on a system within the enterprise. A user registry operates like a directory and contains a list of valid user identities for a particular system or application. A basic user registry contains user identities and their passwords. One example of a user registry is the z/OS Security Server Resource Access Control Facility (RACF) registry. User registries can contain other information as well. For example, a Lightweight Directory Access Protocol (LDAP) directory contains bind distinguished names, passwords, and access controls to data that is stored in LDAP. Other examples of common user registries are a Kerberos key distribution center (KDC) and the OS/400® user profiles registry.

You can also define user registries that exist within other user registries. Some applications use a subset of user identities within a single instance of a user registry. For example, the z/OS Security Server (RACF) registry can contain specific user registries that are a subset of users within the overall RACF user registry. To model this behavior, EIM allows administrators to create two kinds of EIM registry definitions:

- System registry definitions
• Application registry definitions

EIM registry definitions provide information regarding those user registries in an enterprise. The administrator defines these registries to EIM by providing the following information:

• A unique, arbitrary EIM registry name
• The type of user registry

Each registry definition represents a specific instance of a user registry. Consequently, you should choose an EIM registry definition name that helps you to identify the particular instance of the user registry. For example, you could choose the TCP/IP host name for a system user registry, or the host name combined with the name of the application for an application user registry. You can use any combination of alphanumeric characters, mixed case, and spaces to create unique EIM registry definition names.

There are a number of predefined user registry types that EIM provides to cover most operating system user registries. These include:

• AIX®
• Domino - long name
• Domino - short name
• Kerberos
• Kerberos - case sensitive
• LDAP
• Linux
• Policy director
• Novell Directory Server
• OS/400
• Tivoli Access Manager
• RACF
• Windows - local
• Windows domain (Kerberos)
• X.509

**Note:** Although the predefined registry definition types cover most operating system user registries, you may need to create a registry definition for which EIM does not include a predefined registry type. You have two options in this situation. You can either use an existing registry definition which matches the characteristics of your user registry or you can define a private user registry type. For example in the following figure, the administrator followed the process required and defined the type of registry as WebSphere® Third-Party Authentication (LTPA) for the System_A_WAS application registry definition.

In the following figure, the administrator creates EIM registry definitions for user registries representing System A, System B, and System C and a Windows Active Directory that contains users’ Kerberos principals with which users log into their desktop workstations. In addition, the administrator created an application registry definition for WebSphere Lightweight Third-Party Authentication (LTPA), which runs on System A. The registry definition name that the administrator uses helps to identify the specific occurrence of the type of user registry. For example, an IP address or host name is often sufficient for many types of user registries. In this example, the administrator identifies the specific user registry instance by using System_A_WAS as the registry definition name to identify this specific instance of the WebSphere LTPA application. In addition to the name, the administrator also provides the type of registry as System_A.
You can also define user registries that exist within other user registries. For example, the z/OS Security Server (RACF) registry can contain specific user registries that are a subset of users within the overall RACF user registry. For a more detailed example of how this works, see “System and application registry definitions” on page 14.

EIM registry definitions and aliasing

You can also create aliases for EIM registry definitions. You can use predefined alias types or you can define your own alias types to use. The predefined alias types include:

- Domain Name System (DNS) host name
- Kerberos realm
- Issuer distinguished name (DN)
- Root distinguished name (DN)
- TCP/IP address
- LDAP DNS host name
- Other

An alias does not have to be in a specific format. You can enter a value of your own choosing for the type. For example, an application might specify that the administrator assign an alias with an alias type of appl and alias name of source registry. The application can then use the eimGetRegistryNameFromAlias() API and specify the alias type and name for the API to retrieve the user registry the application needs.

This alias support allows programmers to write applications without having to know in advance the arbitrary EIM registry name chosen by the administrator who deploys the application. Application documentation can provide the EIM administrator with the alias name and type that the application uses.
Using this information, the EIM administrator can assign this alias name to the EIM registry definition that represents the actual user registry that the administrator wants the application to use.

When the administrator adds the alias to the EIM registry definition, the application can perform an alias lookup to find the EIM registry name at initialization. The alias lookup allows the application to determine the EIM registry name or names to use as input to the APIs that perform a lookup operation, as discussed in “EIM lookup operation” on page 21.

For example, an application that is written to use EIM may specify either a source registry alias or a target registry alias, or aliases for both. When you assign these aliases to the appropriate registry definitions, the application can perform an alias lookup to find the EIM registry definition or definitions that match the aliases in the application. This alias lookup ensures that the application uses the user registry or user registries that the administrator wants it to use. Based on application requirements, an administrator can assign multiple aliases to a single registry definition.

System and application registry definitions

Some applications use a subset of user identities within a single instance of a user registry. EIM allows administrators to model this scenario by providing two kinds of EIM registry definitions, system and application.

A system registry definition represents a distinct registry within a workstation or server. You can create a system registry definition when the registry in the enterprise has one of the following traits:

- The registry is provided by an operating system, such as AIX, OS/400, or a security management product such as z/OS Security Server Resource Access Control Facility (RACF).
- The registry contains user identities that are unique to a specific application, such as Lotus Notes.
- The registry contains distributed user identities, such as Kerberos principals or Lightweight Directory Access Protocol (LDAP) distinguished names.

An application registry definition is an entry in EIM that you create to describe and represent a subset of user identities that are defined in a system registry. These user identities share a common set of attributes or characteristics that allow them to use a particular application or set of applications. Application registry definitions represent user registries that exist within other user registries. For example, the z/OS Security Server (RACF) registry can contain specific user registries that are a subset of users within the overall RACF user registry. Because of this relationship, you must specify the name of the parent system registry for any application registry definition that you create. You can create an application registry definition when the user identities have the following traits:

- The user identities for the application or set of applications are not stored in a user registry specific to the application or set of applications.
- The user identities for the application or set of applications are stored in a system registry that contains user identities for other applications.

EIM lookup operations perform correctly regardless of whether an EIM administrator defines a registry either as system or application. However, separate registry definitions allow mapping data to be managed on an application basis. The responsibility of managing application-specific mappings can be assigned to an administrator for a specific registry.

For example, the following figure shows how an EIM administrator created a system registry definition to represent a z/OS Security Server RACF registry. The administrator also created an application registry definition to represent the user identities within the RACF registry that use z/OS UNIX System Services (z/OS UNIX). System C contains a RACF user registry that contains information for three user identities, DAY1, ANN1, and SMITH1. Two of these user identities (DAY1 and SMITH1) access z/OS UNIX on System C. These user identities are actually RACF users with unique attributes that identify them as z/OS UNIX users. Within the EIM registry definitions, the EIM administrator defined System_C_RACF to represent the overall RACF user registry. The administrator also defined System_C_UNIX to represent the user identities that have z/OS UNIX attributes.
EIM associations

An EIM association is an entry that you create in an EIM domain to define a relationship between user identities in different user registries. The type of association that you create determines whether the defined relationship is direct or indirect. You can create one of two types of associations in EIM: identifier associations and policy associations. You can use policy associations instead of, or in combination with, identifier associations. How you use associations depends on your overall EIM implementation plan.

Identifier associations

An EIM identifier represents a specific person or entity in the enterprise. An EIM identifier association describes a relationship between an EIM identifier and a single user identity in a user registry that also represents that person. When you create associations between an EIM identifier and all of a person's or entity's user identities, you provide a single, complete understanding of how that person or entity uses the resources in an enterprise.

User identities can be used for authentication, authorization, or both. Authentication is the process of verifying that an entity or person who provides a user identity has the right to assume that identity. Verification is often accomplished by forcing the person who submits the user identity to provide secret or private information associated with the user identity, such as a password. Authorization is the process of ensuring that a properly authenticated user identity can only perform functions or access resources for which the identity has been given privileges. In the past, nearly all applications were forced to use the identities in a single user registry for both authentication and authorization. By using EIM lookup operations, applications now can use the identities in one user registry for authentication while they use associated user identities in a different user registry for authorization. Refer to “EIM lookup operation” on page 21 for more information.

An EIM association is a relationship between an EIM identifier that represents a specific person and a single user identity in a user registry that also represents that person. When you create associations between an EIM identifier and all of a person's or entity's user identities, you provide a single, complete understanding of how that person or entity uses the resources in an enterprise. EIM provides APIs that allow applications to find an unknown user identity in a specific (target) user registry by providing a known user identity in some other (source) user registry. This process is called identity mapping.

In EIM, an administrator can define three different types of associations to describe the relationship between an EIM identifier and a user identity. Identifier associations can be any of the following types:
source, target, or administrative. The type of association that you create is based on how the user identity is used. For example, you create source and target associations for those user identities that you want to participate in mapping lookup operations. Typically, if a user identity is used for authentication, you create a source association for it. You then create target associations for those user identities that are used for authorization.

Before you can create an association, you first must create the appropriate EIM identifier and the appropriate EIM registry definition for the user registry that contains the associated user identity. An association defines a relationship between an EIM identifier and a user identity by using the following information:

- EIM identifier name
- User identity name
- EIM registry definition name
- Association type
- Lookup information to further identity the target user identity in a target association (optional).

An administrator can create different types of associations between an EIM identifier and a user identity based on how the user identity is used. User identities can be used for authentication, authorization, or both.

**Source and target association relationship**

In EIM, there are three types of associations that an administrator can define between an EIM identifier and a user identity. These types are source, target, and administrative associations.

**Source association**

When a user identity is used for authentication, that user identity should have a source association with an EIM identifier. A source association allows the user identity to be used as the source in an EIM lookup operation to find a different user identity that is associated with the same EIM identifier. If a user identity with only a source association is used as the target identity in an EIM lookup operation, no associated user identities are returned. To ensure successful mapping lookup operations for EIM identifiers, source and target associations must be used together for a single EIM identifier.

**Target association**

When a user identity is used for authorization rather than for authentication, that user identity should have a target association with an EIM identifier. A target association allows the user identity to be returned as the result of an EIM lookup operation. If a user identity with only a target association is used as the source identity in an EIM lookup operation, no associated user identities are returned.

It might be necessary to create both a target and a source association for a single user identity. This is required when an individual uses a single system as both a client and a server or for individuals who act as administrators. For example, a user normally authenticates to a Windows platform and runs applications that access an AIX server. Because of the user's job responsibilities, the user must occasionally also log directly into an AIX server. In this situation you would create both source and target associations between the AIX user identity and the person's EIM identifier. User identities that represent end users normally need a target association only.

To ensure successful mapping lookup operations, you need to create at least one source and one or more target associations for a single EIM identifier. Typically, you create a target association for each user identity in a user registry that the person can use for authorization to the system or application to which the user registry corresponds.

The following figure shows an example of a source and a target association. In this example, the administrator created two associations for the EIM identifier John Day to define the relationship between this identifier and two associated user identities. The administrator created a source association for johnday, the WebSphere Lightweight Third-Party Authentication (LTPA) user identity in the System_A_WAS user registry. The administrator also created a target association for jsd1, the OS/400 user profile in the System B user registry. These associations provide a means for applications to obtain an unknown user identity (the target, jsd1) based on a known user identity (the source, johnday) as part of an EIM lookup operation.
Figure 8: EIM target and source associations for the EIM identifier John Day

**Administrative association**

An administrative association for an EIM identifier is typically used to show that the person or entity represented by the EIM identifier owns a user identity that requires special considerations for a specified system. This type of association can be used, for example, with highly sensitive user registries.

Due to the nature of what an administrative association represents, an EIM lookup operation that supplies a source user identity with an administrative association returns no results. Similarly, a user identity with an administrative association is never returned as the result of an EIM lookup operation.

The following figure shows an example of an administrative association. In this example, John Day has one user identity on System A and another user identity on System B, which is a highly secure system. The system administrator wants to ensure that users authenticate to System B by using only the local user registry of this system. The administrator does not want to allow an application to authenticate John Day to the system by using some foreign authentication mechanism. By using an administrative association for the JDay user identity on System B, the EIM administrator can see that John Day owns an account on System B, but EIM does not return information about the JDay identity in EIM lookup operations. Even if applications exist on this system that use EIM lookup operations, they cannot find user identities that have administrative associations.
Policy associations

EIM’s mapping policy support allows an EIM administrator to create and use policy associations to define a relationship between multiple user identities in one or more user registries and a single user identity in another user registry. Policy associations use EIM mapping policy support to create many-to-one mappings between user identities without involving an EIM identifier. You can use policy associations instead of, or in combination with, identifier associations that provide one-to-one mappings between an EIM identifier and a single user identity.

A policy association affects only those user identities for which specific individual EIM associations do not exist. When specific identifier associations exist between an EIM identifier and user identities, then the target user identity from the identifier association is returned to the application performing the lookup operation, even when a policy association exists and the use of policy associations is enabled.

With EIM, you can create three different types of policy associations: default domain, default registry, and certificate filter policy associations. Because you can use policy associations in a variety of overlapping ways, you should have a thorough understanding of EIM mapping policy support and how lookup operations work before you create and use policy associations.

Default domain policy associations

A default domain policy association is one type of policy association that you can use to create many-to-one mappings between user identities. You can use a default domain policy association to map a source set of multiple user identities (in this case, all users in the domain) to a single target user identity in a specified target user registry. In a default domain policy association, all users in the domain are the source of the policy association and are mapped to a single target registry and target user identity.
To use a default domain policy association, you must enable mapping lookups using policy associations for the domain. You must also enable mapping lookups for the target user registry of the policy association. When you configure this enablement, the user registries in the policy association can participate in mapping lookup operations.

The default domain policy association takes effect when a mapping lookup operation is not satisfied by identifier associations, certificate filter policy associations, or default registry policy associations for the target registry. The result is that all user identities in the domain are mapped to the single target user identity as specified by the default domain policy association. For example, you create a default domain policy association with a target user identity of John_Day in target registry Registry_xyz and you have not created any identifier associations or other policy associations that map to this user identity. Therefore, when Registry_xyz is specified as the target registry in lookup operations, the default domain policy ensures that the target user identity of John_Day is returned for all user identities in the domain that do not have any other associations defined for them.

You specify the following to define a default domain policy association:

- **Target registry**: The name of an EIM registry definition which contains the user identity to which all user identities in the domain are to be mapped.
- **Target user**: The name of the user identity that is returned as the target of an EIM mapping lookup operation based on this policy association.

You can define a default domain policy association for each registry in the domain. If two or more domain policy associations refer to the same target registry, you must define unique lookup information for each of these policy associations to ensure that mapping lookup operations can distinguish among them. Otherwise, mapping lookup operations may return multiple target user identities. As a result of these ambiguous results, applications that rely on EIM may not be able to determine the exact target user identity to use.

**Default registry policy associations**

A default registry policy association is one type of policy association that you can use to create many-to-one mappings between user identities. You can use a default registry policy association to map a source set of multiple user identities (in this case those in a single registry) to a single target user identity in a specified target user registry. In a default registry policy association, all users in a single registry are the source of the policy association and are mapped to a single target registry and target user.

To use default registry policy associations, you must enable mapping lookups using policy associations for the domain. You must also enable mapping lookups for the source registry and enable mapping lookups and the use of policy associations for the target user registry of the policy association. When you configure this enablement, the user registries in the policy association can participate in mapping lookup operations. The default registry policy association takes effect when a mapping lookup operation is not satisfied by identifier associations, certificate filter policy associations, or other default registry policy associations for the target registry. The result is that all user identities in the source registry are mapped to the single target user identity as specified by the default registry policy association.

For example, you create a default registry policy association that has a source registry of my_realm.com, which are principals in a specific Kerberos realm. For this policy association, you also specify a target user identity of general_user1 in target registry os/400_system_reg, which is a specific user profile in an OS/400 user registry. In this case, you have not created any identifier associations or policy associations that apply to any of the user identities in the source registry. Therefore, when os/400_system_reg is specified as the target registry and my_realm.com is specified as the source registry in lookup operations, the default registry policy association ensures that the target user identity of general_user1 is returned for all user identities in my_realm.com that do not have any specific identifier associations or certificate filter policy associations defined for them.

You specify the following to define a default registry policy association:
• **Source registry**: This is the registry definition that you want the policy association to use as the source of the mapping. All the user identities in this source user registry are to be mapped to the specified target user of the policy association.

• **Target registry**: The name of an EIM registry definition. The target registry must contain the target user identity to which all user identities in the source registry are to be mapped.

• **Target user**: The name of user identity that is returned as the target of an EIM mapping lookup operation based on this policy association.

You can define more than one default registry policy association. If two or more policy associations with the same source registry refer to the same target registry, you must define unique lookup information for each of these policy associations to ensure that mapping lookup operations can distinguish among them. Otherwise, mapping lookup operations may return multiple target user identities. As a result of these ambiguous results, applications that rely on EIM may not be able to determine the exact target identity to use.

**Certificate filter policy associations**

A type of policy association that you can use to create many-to-one mappings between user identities. You can use a certificate filter policy association to map a source set of certificates to a single target user identity in a specified target user registry.

In a certificate filter policy association, you specify a set of certificates in a single X.509 registry as the source of the policy association. These certificates are mapped to a single target registry and target user that you specify. Unlike a default registry policy association in which all users in a single registry are the source of the policy association, the scope of a certificate filter policy association is more flexible. You can specify a subset of certificates in the registry as the source. The certificate filter that you specify for the policy association is what determines its scope.

**Note:** When you want to map all the certificates in an X.509 user registry to a single target user identity, create and use a default registry policy association.

To use certificate filter policy associations, you must enable mapping lookups using policy associations for the domain. You must also enable mapping lookups for the source registry and enable mapping lookups and the use of policy associations for the target user registry of the policy association. When you configure this enablement, the user registries in the policy association can participate in mapping lookup operations.

When a digital certificate is the source user identity in an EIM mapping lookup operation (after the requesting application uses `eimFormatUserIdentity` to format the user identity name), EIM first checks to see if there is an identifier association between an EIM identifier and the specified user identity. If none exist, EIM then compares the DN information in the certificate against the DN or partial DN information specified in the filter for the policy association. If the DN information in the certificate satisfies the criteria of the filter, EIM returns the target user identity that the policy association specified. The result is that certificates in the source X.509 registry that satisfy the certificate filter criteria are mapped to the single target user identity as specified by the certificate filter policy association.

You specify the following information to define a certificate filter policy association:

• **Source registry**: The source registry definition that you specify must be an X.509 type user registry. The certificate filter policy creates an association between user identities in this X.509 user registry and a single, specific target user identity. The association is applied to only those user identities in the registry that meet the criteria of the certificate filter that you specify for this policy.

• **Certificate filter**: Defines a set of similar user certificate attributes. The certificate filter policy association maps any certificates with these defined attributes in the X.509 user registry to a specific target user identity. You specify the filter based on a combination of the Subject distinguished name (SDN) and the Issuer distinguished name (IDN) that matches the certificates that you want to use as the source of the mapping. The certificate filter that you specify for the policy must already exist in the EIM domain.

• **Target registry**: The target registry definition that you specify is the user registry that contains the user identity to which you want to map the certificates that match the certificate filter.
• Target user: The target user is the name of the user identity that is returned as the target of an EIM mapping lookup operation based on this policy association.

Lookup information

You can provide optional data called lookup information to further identify a target user identity. This target user identity can be specified either in an identifier association or in a policy association. Lookup information is a unique character string that either the eimGetTargetFromSource API or the eimGetTargetFromIdentifier API can use during a mapping lookup operation to further refine the search for the target user identity that is the object of the operation. Data that you specify for lookup information corresponds to the registry users additional information parameter for these APIs.

Lookup information is necessary only when a mapping lookup operation can return more than one target user identity. A mapping lookup operation can return multiple target user identities when one or more of the following situations exist:

• An EIM identifier has multiple individual target associations to the same target registry.
• More than one EIM identifier has the same user identity specified in a source association and each of these EIM identifiers has a target association to the same target registry, although the user identity specified for each target association may be different.
• More than one default domain policy association specifies the same target registry.
• More than one default registry policy association specifies the same source registry and the same target registry.
• More than one certificate filter policy association specifies the same source X.509 registry, certificate filter, and target registry.

Note: A mapping lookup operation that returns more than one target user identity can create problems for EIM-enabled applications, including OS/400 applications and products, that are not designed to handle these ambiguous results. Consequently, you might consider redefining associations for the domain to ensure that a mapping lookup operation can return a single target user identity to ensure that base OS/400 applications can successfully perform lookup operations and map identities.

You can use lookup information to avoid situations where it is possible for mapping lookup operations to return more than one target user identity. To prevent mapping lookup operations from returning multiple target user identities, you must define unique lookup information for each target user identity in each association. This lookup information must be provided to the mapping lookup operation to ensure that the operation can return a unique target user identity. Otherwise, applications that rely on EIM may not be able to determine the exact target identity to use.

For example, you have an EIM identifier named John Day who has two user profiles on System A. One of these user profiles is JDUSER on System A and another is JDSECADM, which has security administrator special authority. There are two target association for the John Day identifier. One of these target associations is for the JDUSER user identity in the target registry of System_A and has lookup information of user authority specified for JDUSER. The other target association is for the JDSECADM user identity in the target registry of System_A and has lookup information of security officer specified for JDSECADM.

If a mapping lookup operation does not specify any lookup information, the lookup operation returns both the JDUSER and the JDSECADM user identities. If a mapping lookup operation specifies lookup information of user authority, the lookup operation returns the JDUSER user identity only. If a mapping lookup operation specifies lookup information of security officer, the lookup operation returns the JDSECADM user identity only.

If you delete the last target association for a user identity (whether it is an identifier association or a policy association), the target user identity and all lookup information is deleted from the domain as well.

EIM lookup operation

An application or an operating system uses an EIM API to perform a lookup operation so that the application or operating system can map from one user identity in one registry to another user identity in
another registry. An EIM lookup operation is a process through which an application or operating system finds an unknown associated user identity in a specific target registry by supplying some known and trusted information. Applications that use EIM APIs can perform these EIM lookup operations on information only if that information is stored in the EIM domain. An application can perform one of two types of EIM lookup operations based on the type of information the application supplies as the source of the EIM lookup operation: a user identity or an EIM identifier.

When applications or operating systems use the eimGetTargetFromSource API to obtain a target user identity for a given target registry, they must supply a user identity as the source of the lookup operation. To be used as the source in a EIM lookup operation, a user identity must have either an identifier source association defined for it or be covered by a policy association. When an application or operating system uses this API, the application or operating system must supply these pieces of information:

- A user identity as the source, or starting point of the operation.
- The EIM registry definition name for the source user identity.
- The EIM registry definition name that is the target of the EIM lookup operation. This registry definition describes the user registry that contains the user identity that the application is seeking.

When applications or operating systems use the eimGetTargetFromIdentifier API to obtain a user identity for a given target registry, they must supply an EIM identifier as the source of the EIM lookup operation. When an application uses this API, the application must supply the following pieces of information:

- A user identity as the source, or starting point of the operation.
- The EIM registry definition name that is the target of the EIM lookup operation. This registry definition describes the user registry that contains the user identity that the application is seeking.

For a user identity to be returned as the target of either type of EIM lookup operation, the user identity must have a target association defined for it. This target association can be in the form of an identifier association or a policy association.

The supplied information is passed to EIM and the lookup operation searches for and returns any target user identities, by searching EIM data in the following order:

1. Identifier target association for an EIM identifier. The EIM identifier is identified in one of two ways: It is supplied by the eimGetTargetFromIdentifier API. Or, the EIM identifier is determined from information supplied by the eimGetTargetFromSource API.
2. Certificate filter policy association.
3. Default registry policy association.
4. Default domain policy association.
Figure 10: EIM lookup operation general processing flow chart

The lookup operation search flows in this manner:

1. The lookup operation checks whether mapping lookups are enabled. The lookup operation determines whether mapping lookups are enabled for the specified source registry, the specified target registry, or both specified registries. If mapping lookups are not enabled for one or both of the registries, then the lookup operation ends without returning a target user identity.

2. The lookup operation checks whether there are identifier associations that match the lookup criteria. If an EIM identifier was provided, the lookup operation uses the specified EIM identifier name. Otherwise, the lookup operation checks whether there is a specific identifier source association that matches the supplied source user identity and source registry. If there is one, the lookup operation uses it to determine the appropriate EIM identifier name. The lookup operation then uses the EIM identifier name to search for an identifier target association for the EIM identifier that matches the specified target EIM registry definition name. If there is an identifier target association that matches, the lookup operation returns the target user identity defined in the target association.

3. The lookup operation checks whether the use of policy associations are enabled. The lookup operation checks whether the domain is enabled to allow mapping lookups using policy associations. The lookup operation also checks whether the target registry is enabled to use policy associations. If the domain is
not enabled for policy associations or the registry is not enabled for policy associations, then the lookup operation ends without returning a target user identity.

4. The lookup operation checks for certificate filter policy associations. The lookup operation checks whether the source registry is an X.509 registry type. If it is an X.509 registry type, the lookup operation checks whether there is a certificate filter policy association that matches the source and target registry definition names. The lookup operation checks whether there are certificates in the source X.509 registry that satisfy the criteria specified in the certificate filter policy association. If there is a matching policy association and there are certificates that satisfy the certificate filter criteria, the lookup operation returns the appropriate target user identity for that policy association.

5. The lookup operation checks for default registry policy associations. The lookup operation checks whether there is a default registry policy association that matches the source and target registry definition names. If there is a matching policy association, the lookup operation returns the appropriate target user identity for that policy association.

6. The lookup operation checks for default domain policy associations. The lookup operation checks whether there is a default domain policy association defined for the target registry definition. If there is a matching policy association, the lookup operation returns the associated target user identity for that policy association.

7. The lookup operation is unable to return any results.

When an application supplies a user identity as the source, the application also must supply the EIM registry definition name for the source user identity and the EIM registry definition name that is the target of the EIM lookup operation. To be used as the source in a EIM lookup operation, a user identity must have a source association defined for it. Refer to “EIM associations” on page 15 for more information.

When an application supplies an EIM identifier as the source of the EIM lookup operation, the application must also supply the EIM registry definition name that is the target of the EIM lookup operation. For a user identity to be returned as the target of either type of EIM lookup operation, the user identity must have a target association defined for it.

The supplied information is passed to the EIM domain controller where all EIM information is stored and the EIM lookup operation searches for the source association that matches the supplied information. Based on the EIM identifier (supplied to the API or determined from the source association information), the EIM lookup operation then searches for a target association for that identifier that matches the target EIM registry definition name.

In Figure 10, the user identity johnday authenticates to the Websphere Application Server by using Lightweight Third-Party Authentication (LPTA) on System A. The Websphere Application Server on System A calls a native program on System B to access data on System B. The native program uses an EIM API to perform an EIM lookup operation based on the user identity on System A as the source of the operation. The application supplies the following information to perform the operation: johnday as the source user identity, System_A_WAS as the source EIM registry definition name, and System_B as the target EIM registry definition name. This source information is passed to the EIM domain controller and the EIM lookup operation finds a source association that matches the information. Using the EIM identifier name, the EIM lookup operation searches for a target association for the John Day identifier that matches the target EIM registry definition name for System_B. When the matching target association is found, the EIM lookup operation returns the jsd1 user identity to the application.
Mapping policy support and enablement

EIM mapping policy support allows you to use policy associations as well as specific identifier associations in an EIM domain. You can use policy associations instead of, or in combination with, identifier associations.

EIM mapping policy support provides a means of enabling and disabling the use of policy associations for the entire domain, as well as for each specific target user registry. EIM also allows you to set whether a specific registry can participate in mapping lookup operations in general. Consequently, you can use mapping policy support to more precisely control how mapping lookup operations return results.

The default setting for an EIM domain is that mapping lookups that use policy associations are disabled for the domain. When the use of policy associations is disabled for the domain, all mapping lookup operations for the domain return results only by using specific, identifier associations between user identities and EIM identifiers.

The default setting for each individual registry is that mapping lookup participation is enabled and the use of policy associations is disabled. When you enable the use of policy associations for an individual target registry, you must also ensure that this setting is enabled for the domain.

You can configure mapping lookup participation and the use of policy associations for each registry in one of the following ways:

- Mapping lookup operations can not be used for the specified registry at all. In other words, an application that performs a mapping lookup operation involving that registry will fail to return results.
• Mapping lookup operations can use specific identifier associations between user identities and EIM identifiers only. Mapping lookups are enabled for the registry, but the use of policy associations is disabled for the registry.
• Mapping lookup operations can use specific identifier associations when they exist and policy associations when specific identifier associations do not exist (all settings are enabled).

### EIM access control

An EIM user is a user who possesses EIM access control based on their membership in a predefined Lightweight Directory Access Protocol (LDAP) user group for a specific domain. Specifying EIM access control for a user adds that user to a specific LDAP user group for a particular domain. Each LDAP group has authority to perform specific EIM administrative tasks for that domain. Which and what type of administrative tasks, including lookup operations, an EIM user can perform is determined by the access control group to which the EIM user belongs.

EIM access controls allow a user to perform specific administrative tasks or EIM lookup operations. Only users with EIM administrator access are allowed to grant or revoke authorities for other users. EIM access controls are granted only to user identities that are known to the EIM domain controller.

The following are brief descriptions of the functions that each EIM access control group can perform:

**Lightweight Directory Access Protocol (LDAP) administrator**
This access control allows the user to configure a new EIM domain. A user with this access control can perform the following functions:
- Create a domain
- Delete a domain
- Create and remove EIM identifiers
- Create and remove EIM registry definitions
- Create and remove source, target, and administrative associations
- Perform EIM lookup operations
- Retrieve associations, EIM identifiers, and EIM registry definitions
- Add, remove, and list EIM authority information

**EIM administrator**
This access control allows the user to manage all of the EIM data within this EIM domain. A user with this access control can perform the following functions:
- Delete a domain
- Create and remove EIM identifiers
- Create and remove EIM registry definitions
- Create and remove source, target, and administrative associations
- Perform EIM lookup operations
- Retrieve associations, EIM identifiers, and EIM registry definitions
- Add, remove, and list EIM authority information

**EIM identifiers administrator**
This access control allows the user to add and change EIM identifiers and manage source and administrative associations. A user with this access control can perform the following functions:
- Create an EIM identifier
- Add and remove source associations
- Add and remove administrative associations
- Perform EIM lookup operations
- Retrieve associations, EIM identifiers, and EIM registry definitions
EIM mapping lookup
This access control allows the user to conduct EIM lookup operations. A user with this access control can perform the following functions:

• Perform EIM lookup operations
• Retrieve associations, EIM identifiers, and EIM registry definitions

EIM registries administrator
This access control allows the user to manage all EIM registry definitions. A user with this access control can perform the following functions:

• Add and remove target associations
• Perform EIM lookup operations
• Retrieve associations, EIM identifiers, and EIM registry definitions

EIM registry X administrator
This access control allows the user to manage a specific EIM registry definition. Membership in this access control group also allows the user to add and remove target associations only for a specified user registry definition. To take full advantage of mapping lookup operations and policy associations, a user with this access control should also have EIM mapping operations access control. This access control allows a user to:

• Create, remove, and list target associations for the specified EIM registry definitions only
• Add and remove default domain policy associations
• Add and remove policy associations for the specified registry definitions only
• Add certificate filters for the specified registry definitions only
• Enable and disable mapping lookups for the specified registry definitions only
• Add and remove policy associations only for the specified registries
• Retrieve EIM identifiers
• Retrieve identifier associations and certificate filters for the specified registry definitions only
• Add and remove target associations for the specific EIM registry definition
• Perform EIM lookup operations
• Retrieve EIM registry definition information for the specified registry definitions only

Each of the following tables is organized by the EIM task that the API performs. Each table displays each EIM API, the different EIM access controls, and the access each of these access controls has to certain EIM functions. Keep in mind there are also Java versions of these APIs, in case you need to work with z/OS applications written in Java. For more information on Java APIs, see “Java APIs” on page 161.

For eimAddAssociation() and eimRemoveAssociation() APIs there are four parameters that determine the type of association that is either being added or removed. The authority to these APIs differs based on the type of association specified in these parameters. In the following table, the type of association is included for each of these APIs.

<table>
<thead>
<tr>

Chapter 3. Migration considerations

This chapter discusses migration issues. Your plan for migrating to a new level of EIM should include information from a variety of sources. These sources of information describe topics such as coexistence service, hardware and software requirements, migration actions, and interface changes. This section should be referenced early in the planning stages as you migrate from one release to another.

Migration from release to release

Migration from EIM Release 6

There are special considerations for applications that will be shared between different releases of z/OS. Prior to z/OS V1R7, EIM application needed to be APF authorized. For z/OS V1R7 or later, the application should not be APF authorized. The one exception is when the application is shared between a down level system and a z/OS V1R7 or later system. The application must remain APF authorized in order for it to work on the down level system. For more information, see “Preparing to run an EIM application” on page 73.

Migration from EIM Release 5 - Starting point

EIM domain controller

Before an EIM domain controller can be migrated to the next release, the LDAP administrator must apply the enhanced schema elements to the LDAP directory. For more information on the EIM domain controller, see “Planning considerations for an EIM domain controller” on page 41. For more information on running EIM on z/OS, see “Steps for installing and configuring the EIM domain controller on z/OS” on page 45.

EIM client applications

Existing EIM lookup and administration applications work unchanged with the enhanced domain controller. However, the new policy and certificate support are not available to those applications. New EIM lookup applications and new administration applications work only with the enhanced domain controller.

For more information on EIM client applications, see “Planning for EIM client applications” on page 35.

Removal of SETROPTS EIMREGISTRY/NOEIMREGISTRY

In z/OS V1R4 and R5 the SETROPTS command was used to make an in-storage copy of the local registry name. In z/OS V1R6, the registry name is no longer kept in storage but retrieved once per EIM application that uses the local registry name. The SETROPTS command is no longer needed to make the in-storage copy. For that reason, the EIMREGISTRY/NOEIMREGISTRY keywords are no longer available on the SETROPTS command.
Chapter 4. Planning for EIM

This chapter provides the information you need to understand the task of implementing EIM on your IBM server platform. This chapter also provides the information you need to:

• Understand the task of implementing EIM
• Determine which skills are required to complete your implementation team and create your own implementation plan

This chapter explores the following topics:

• “Identifying skill requirements” on page 33
  – “Team members” on page 33
• “Planning for EIM client applications” on page 35
  – “Planning for an EIM domain” on page 36
  – “Planning for EIM registries” on page 37
  – “Planning considerations for identifiers” on page 38
  – “Planning considerations for associations” on page 39
  – “Accessing the EIM domain” on page 40
• “Planning considerations for an EIM domain controller” on page 41
• “Planning EIM administration tools” on page 42
• “Customizing EIM on your operating system” on page 43
• “Task roadmap for implementing EIM” on page 43

Before you begin

The EIM administrator needs to plan carefully for the EIM domain. Before setting up the domain, consider the following:

• What applications will refer to the EIM domain?
• On what systems will the applications run?
• Which system or application registries need to participate in the domain?
• What identifiers do you need to add?
• What associations need to be added between the identifiers and the user IDs in the registries?

Identifying skill requirements

The implementation of EIM requires the interaction of several software products, each with its own required skills. This means that your team can consist of people from several different disciplines, particularly if you work with a large organization.

This section provides the information you need to determine which skills are required to complete your implementation. These skills are presented as job titles for people who specialize in those skills. For example, a task requiring MVS skills is referred to as a task for a "z/OS system programmer". Consequently, if some of your team members have multiple skills you might require fewer individuals to complete your team.

Team members

The following describes the responsibilities and roles involved in administering EIM. It also defines potential team members for installing and configuring prerequisite products, and setting up EIM.
An EIM domain can be administered by the LDAP administrator alone, by an EIM administrator, or this responsibility can be divided so the domain can be administered by all of the EIM administrators. Therefore it is advisable to appoint these administrators early and involve them in your planning.

**Tip**

EIM administrators play an important role in your organization. The decisions they make when creating associations between an identifier and a user ID in a registry can determine who can access your computer systems and what privileges they have when doing so. IBM recommends that you give this authority to those individuals in whom you have a high level of trust.

The following table lists team members (alphabetically) and the tasks and skills needed for setting up EIM:

<table>
<thead>
<tr>
<th>Role</th>
<th>Tasks</th>
<th>Required Skills</th>

</table>

Planning for EIM client applications

Before you begin

If you are installing an IBM or vendor-written application that exploits EIM, check the product documentation for the hardware and software prerequisites, the specific installation procedures, and configuration procedures. Generally, the applications that use EIM must run on a system where the EIM APIs and the LDAP client are installed.

The EIM APIs are supported on the following hardware and software platforms:

Table 10: EIM APIs software and hardware prerequisites

<table>
<thead>

## Tip

If you are writing your own application to use EIM, the preceding table can provide guidance on which platforms the applications can use.

Planning activities for an EIM application include:

1. Identifying the information that is stored in the EIM domain as well as hardware and software prerequisites. For example, the next couple of sections describes what information needs to go into an EIM domain

2. Using the worksheets for recording the information required by the EIM application you are working with. The EIM administrator can take the information from the worksheets and perform the tasks necessary to set up an EIM domain

### Planning for an EIM domain

Planning for EIM application begins with the EIM domain. This domain might represent your entire enterprise, a division, a department, or even an application. Plan for the domain to be shared between many applications in order to gain the maximum benefit from having a centralized repository for mapping information.

When setting up your domain you must:

1. Determine whether or not there is an existing domain to use, or if one should be created
2. Name the domain (you can also provide an optional description)

Record your answers in Table 11 on page 36.

### Table 11: Domain worksheet for creating an EIM domain

<table>
<thead>
<tr>
<th>Parameter name and description</th>
<th>Customized value</th>
</tr>
</thead>
<tbody>
<tr>
<td>description — A string that provides a description of the object you are acting upon.</td>
<td></td>
</tr>
<tr>
<td>domainDN — The distinguished name of the EIM domain. This consists of:</td>
<td></td>
</tr>
<tr>
<td>• ibm-eimDomainName=</td>
<td></td>
</tr>
<tr>
<td>• domainName — The name of the EIM domain you are creating, for example: My Domain. (This could be the name of a company, a department, or an application that uses the domain.)</td>
<td></td>
</tr>
<tr>
<td>• parentDN — The distinguished name for the entry immediately above the given entry in the directory information tree hierarchy, for example: o=ibm,c=us</td>
<td></td>
</tr>
</tbody>
</table>

Example:

ibm-eimDomainName=MyDomain, o=ibm, c=us
Planning for EIM registries

The registries that must be defined in an EIM domain are the ones required by the EIM lookup and administration applications that will be using the domain. The registries can represent operating system registries such as RACF or OS/400, a distributed registry such as Kerberos, or a subset of a system registry that is used exclusively by an application.

Consider the following when planning for your registries:

- An EIM domain can contain registries that exist on any platform. A domain controller on z/OS might contain registries for non-z/OS platforms and an EIM domain controller on a non-z/OS platform might contain a z/OS registry, such as RACF.
- The names given to an EIM registry can represent the type of registry, the system the actual registry is on, its network address or its physical location in your enterprise.
- The number of registries that can be defined in a domain is limited by the size of the LDAP directory server where the EIM domain is stored.

Tips

- Since there might be many registries to consider (source and target), you can use the following worksheet to accommodate some of your planning tasks, such as recording the registries the EIM application uses. (Note that an application might not use all of the available types of associations.) The worksheet can also be used to record a registry alias used by the application. You can fill out one of these worksheets for each application using the EIM domain.
- The installation and configuration information for the application should tell you what types of registries it requires, whether or not registry aliases are used, and the type of associations between the registry user identities and EIM identifiers the application requires.

Developing an identity mapping plan

A critical part of the initial Enterprise Identity Mapping (EIM) implementation planning process requires that you determine how you want to use identity mapping in your enterprise. There are two methods that you can use to map identities in EIM:

**Identifier associations**

Describe the relationships between an EIM identifier and the user identities in user registries that represent that person. An identifier association creates a direct one-to-one mapping between an EIM identifier and a specific user identity. You can use identifier associations to indirectly define a relationship between user identities through the EIM identifier.

If your security policy requires a high degree of detailed accountability, you may need to use identifier associations almost exclusively for your identity mapping implementation. Because you use identity associations to create one-to-one mappings for the user identities that users own, you can always determine exactly who performed an action on an object or on the system.

**Policy associations**

Describe a relationship between multiple user identities and a single user identity in a user registry. Policy associations use EIM mapping policy support to create many-to-one mappings between user identities without involving an EIM identifier.

Policy associations can be useful when you have one or more large groups of users who need access to systems or applications in your enterprise where you do not want them to have specific user identities for gaining this access. For example, you maintain a Web application that access a specific internal application. You may not want to set up hundreds or thousands of user identities to
authenticate users to this internal application. In this situation, you may want to configure identity mapping such that all the users of this Web application are mapped to a single user identity with the minimum level of authorization required to run the application. You can do this type of identity mapping by using policy associations.

You may decide to use identifier associations to provide the best control of the user identities in your enterprise while gaining the largest degree of streamlined password management. Or, you may decide to use a mixture of policy associations and identifier associations, where appropriate, while you maintain specific control over user identities for administrators. Regardless of what type of identity mapping you decide best meets your business needs and properly fits your security policy, you need to create an identity mapping plan to ensure that you implement identity mapping appropriately.

To create an identity mapping plan, you need to develop an EIM identifier naming plan and plan EIM associations.

**Planning considerations for identifiers**

Part of your planning activities for an EIM application focuses on the users of the application who need an identifier in the EIM domain. Consequently, to ease administration it is important that you create unique identifiers. When planning your EIM identity mapping needs, you can create unique EIM identifiers for users of EIM-enabled applications and operating systems in your enterprise when you want to create one-to-one mappings between user identities for a user. By using identifier associations to create one-to-one mappings you can maximize the password management benefits that EIM provides.

**Tip**

For a domain that does not contain a large number of identifiers you might be able to use the actual names. However, for a domain containing a large number of identifiers, you can use an employee number for the identifier and use the real name in the identifier as an alias. Using an employee number allows an administrator to add two employees who happen to have the same name.

The naming plan that you develop depends on your business needs and preferences; the only requirement for EIM identifier names is that they be unique. Some companies may prefer to use each person's full, legal name; other companies may prefer to use a different type of data, such as each person's employee number. If you want to create EIM identifier names based on each person's full name, you may anticipate possible name duplication. How you handle potential duplicate identifier names is a matter of personal preference. You may want to handle each case manually by adding a predetermined character string to each identifier name to ensure uniqueness; for example, you might decide to add each person's department number.

As part of developing an EIM identifier naming plan, you need to decide on your overall identity mapping plan. Doing so can help you to decide when you need to be using identifiers and identifier associations versus using policy associations for mapping identities within your enterprise. To develop your EIM identifier naming plan, you can use the following work sheet to help you gather information about the user identities in your organization and to plan EIM identifiers for the user identities. The work sheet represents the kind of information the EIM administrator needs to know when he creates EIM identifiers or policy associations for the users of an application. The identifier description and additional information fields are free-form and can be used to provide descriptive information about the user.

**Table 13: Identifier worksheet to help with planning considerations for identifiers**

<table>
<thead>
<tr>
<th>Unique name</th>
<th>Identifier alias</th>
<th>Identifier description</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

An application that is written to use EIM may specify an alias that it uses to find the appropriate EIM identifier for the application, which the application may use in turn to determine a specific user identity to use. You need to check the documentation for your applications to determine whether you need to specify one or more aliases for the identifier. The EIM identifier or user identity description fields are free form and can be used to provide descriptive information about the user.
You do not need to create EIM identifiers for all members of your enterprise at one time. After creating an initial EIM identifier and using it to test your EIM configuration, you can create additional EIM identifiers based on your organization's goals for using EIM. For example, you can add EIM identifiers on a departmental or area basis. Or, you can add EIM identifiers as you deploy additional EIM applications.

After you gather the information that you need to develop an EIM identifier naming plan, you can plan associations for your user identities.

**Planning considerations for associations**

Associations are entries that you create in an EIM domain to define a relationship between user identities in different user registries. You can create one of two types of associations in EIM: identifier associations to define one-to-one mappings and policy associations to define many-to-one mappings. You can use policy associations instead of, or in conjunction with, identifier associations.

The specific types of associations that you choose to create depends on how a user uses a particular user identity, as well as your overall identity mapping plan.

You can create any of the following types of identifier associations:

**Target associations**
Associations for users that normally only access this system as a server from some other client system. This type of association is used when an application performs mapping lookup operations.

**Source associations**
You define source associations when the user identity is the first one that a user provides to sign on to the system or network. This type of association is used when an application performs mapping lookup operations.

**Administrative associations**
You define administrative associations when you want to be able to track the fact that the user identity belongs to a specific user, but do not want the user identity to be available to mapping lookup operations. You can use this type of association to track all the user identities that a person uses in the enterprise.

A policy association always defines a target association.

It is possible for a single registry definition to have more than one type of association depending on how the user registry that it refers to is used. Although there are no limits to the numbers of, or the combinations of, associations that you can define, keep the number to a minimum to simplify the administration of your EIM domain.

Typically, an application will provide guidance on which registry definitions it expects for source and target registries, but not the association types. Each end user of the application needs to be mapped to the application by at least one association. This association can be a one-to-one mapping between their unique EIM identifier and a user identity in the required target registry or a many-to-one mapping between a source registry of which the user identity is a member and the required target registry. Which type of association you use depends on your identity mapping requirements and the criteria the application provides.

**Tips**

- Only add those associations to an EIM domain that are required by the EIM applications that are using the domain. There might be some user IDs in a physical registry that don't have mappings within an EIM domain.

  The number of associations that can be defined in a domain is limited by the size of the LDAP directory server where the EIM domain is stored. There is no hard limit to the number of associations that can be defined between an identifier and user IDs, and between a user ID and identifiers.

- While there are no limits to the combinations of associations that can be defined, it is best to keep the number to a minimum to simplify the administration of your EIM domain.

- The application provides guidance on the registry types it expects, the association types required, and if additional information must be defined for target associations.
As you plan for your EIM applications, use the following worksheets as a guideline for the kind of information the EIM administrator needs to set up the associations. For each end user of the application, there needs to be at least one association between their unique identifier and a user ID in the required registry.

### Accessing the EIM domain

To access an EIM domain you must:

1. Be able to bind to the EIM domain controller

You must first determine the appropriate bind mechanism to connect to the domain controller. EIM APIs support several different mechanism for establishing a connection with the EIM domain controller, each providing a different level of authentication and encryption of the connection. The possible choices are:

**Simple Binds**

A simple bind is an LDAP connection where an LDAP client provides a bind distinguished name and a bind password to the server for authentication. The bind distinguished name and bind password are defined by the administrator in the LDAP directory.

**Server authentication with SSL - server side authentication**

An LDAP server can be configured for SSL or TLS secure connection. The LDAP client and server use digital certificates to encrypt the connection. Only the LDAP server is authenticated. A bind distinguished name and password are used to authenticate the end user.

**Client authentication using SSL**

Provides an additional level of authentication. The LDAP server is configured to require both the LDAP client and server to be authenticated before a connection is established. Digital certificates are used by the LDAP client instead of bind distinguished names and passwords, and the connection is encrypted.
Kerberos authentication

An LDAP client can be authenticated to the server using Kerberos, which is a trusted third-party, private key, network authentication system.

The choice of a bind mechanism is based on the level of security required by the EIM application and the authentication mechanisms supported by the LDAP server hosting the EIM domain. The LDAP server might also require additional configuration to enable the desired authentication mechanism. You must check the documentation (for the LDAP server you are using for your domain controller) for details on how to perform the configuration.

2. Make sure that the bind subject is a member of an EIM authority group. Refer to “EIM access control” on page 26 for more information.

To access the EIM domain, you must belong to an EIM-defined LDAP access control group or be the LDAP administrator. There are several access control groups that are involved in maintaining an EIM domain. Members of the groups have the ability to update or view different portions of the EIM domain. For information on team members for these groups, see “Team members” on page 33.

Tip

Use the following worksheet as a guide when considering the information needed by the application to access the EIM domain. The EIM application provides guidance on the types of bind mechanisms and the EIM authorities it requires of end users. The values entered here are used by the LDAP administrator to define the bind identity to the LDAP directory server, and the EIM administrator to give the bind identity access to the EIM domain. EIM applications that perform lookups typically require EIM mapping operations authority.

<table>
<thead>
<tr>

<td></td>
</tr>
</tbody>
</table>

Planning considerations for an EIM domain controller

Restriction: EIM requirements on LDAP include the following:

- An LDAP directory server that supports the LDAP (Version 3) protocol. It must also understand the following attributes:
  - ibm-entryUUID attribute
  - ibmattributetypes: acIEntry, acIPropagate, acISource, entryOwner, ownerPropagate, ownerSource
  - New attribute types and object classes for EIM (schema updates)

Table 19 on page 41 lists the LDAP servers that can be used as an EIM domain controller.

<table>
<thead>
<tr>
<th>Table 19: Software and hardware worksheet to help in planning for your EIM domain controller</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAP servers</td>
</tr>
<tr>
<td>IBM Directory Server v5.1</td>
</tr>
<tr>
<td>IBM Tivoli Directory Server LDAP server</td>
</tr>
<tr>
<td>OS/400 Directory Services</td>
</tr>
</tbody>
</table>
After reviewing the LDAP directory servers available to you, you can record your choice in the following worksheet.

<table>
<thead>
<tr>
<th>Table 20: Information needed for LDAP administration</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Parameter name and description</strong></td>
</tr>
<tr>
<td>ldapHost — This consists of:</td>
</tr>
<tr>
<td>• The string ldap:// or ldaps://</td>
</tr>
<tr>
<td>• The host name or IP address</td>
</tr>
<tr>
<td>• The port number (this is optional)</td>
</tr>
<tr>
<td>Example:</td>
</tr>
<tr>
<td>ldap://some.ldap.host:389</td>
</tr>
<tr>
<td>ldaps://some.ldap.host</td>
</tr>
</tbody>
</table>

Rules:

1. The LDAP server must be configured for your desired bind mechanisms in order for them to operate successfully. Refer to “Accessing the EIM domain” on page 40 for more information.

2. Before an EIM domain controller can be migrated to the next release, the LDAP administrator must apply the enhanced schema elements to the LDAP directory.

3. New EIM lookup applications and administration applications (introduced in z/OS V1R6 or later) will work only with the enhanced domain controller. Existing EIM administration applications continue to work with the enhanced domain controller. However, the new policy and certificate support are not available. For more information regarding EIM client applications, see “Planning for EIM client applications” on page 35.

Planning EIM administration tools

Some basic steps that must be performed in order to set up an EIM domain are:

1. Creating the domain and define the EIM administrator
2. Creating the registries used by the applications
3. Adding the identifiers
4. Adding the associations

The EIM administrator uses the data recorded in the worksheets provided to perform these tasks. These worksheets are located at “Planning for EIM client applications” on page 35.

Currently, IBM offers several tools an administrator can use to manage the content of an EIM domain, such as the iSeries Navigator or the z/OS eimadmin utility. Software vendors might also offer administration tools in the future. More information can be found in product documentation about the hardware and software prerequisites for the tools, installation, and configuration procedures.

Rule: Generally, administration tools must run on a system where the EIM APIs and the LDAP client are installed.

If you plan to use the z/OS eimadmin utility, remember it is part of z/OS Integrated Security Services Enterprise Identity Mapping. (The eimadmin command is issued from the z/OS UNIX System Services shell.)
Customizing EIM on your operating system

The platform that supports EIM might provide some unique customizations to allow EIM applications to take advantage of operating system specific features. For example, on z/OS the z/OS Security Server RACF provides RACF profiles that allow a security administrator to define the EIM domain used by an application and the necessary bind credentials.

Task roadmap for implementing EIM

Table 21 on page 43 shows the tasks and associated procedures for implementing EIM on z/OS. These tasks will constitute a major part of your implementation plan. Your implementation plan should include major tasks, responsible parties, and a realistic estimate of time and effort required. The major tasks for implementing EIM are provided here as a basis for you to build your own plan.

<table>
<thead>
<tr>
<th>Tasks</th>

</tbody>
</table>
Chapter 5. Setting up EIM on z/OS

If you are using EIM on z/OS, many of the topics discussed previously are still applicable. This chapter additionally (and specifically) explores:

- “Domain authentication methods” on page 53
- “Steps for installing and configuring the EIM domain controller on z/OS” on page 45
- “Installing and configuring EIM on z/OS” on page 47
- “Configuring z/OS to participate in an EIM domain” on page 48
- “Steps for using the eimadmin utility to manage an EIM domain” on page 50
- “Installation considerations for applications” on page 55

It also explores topics about ongoing administration, such as:

- “Managing registries” on page 56
  - “Adding a system and application registry” on page 56
  - “Removing a registry” on page 56
- “Working with registry aliases” on page 57
  - “Assigning an alias” on page 57
  - “Removing an alias” on page 57
  - “Assigning an alias name to a different registry” on page 58
- “Adding a new user” on page 58
  - “Adding an identifier” on page 58
  - “Adding associations” on page 59
- “Removing a user” on page 59
  - “Removing associations” on page 59
  - “Removing an identifier” on page 60
- “Changing access authority” on page 60
  - “Adding access authorities” on page 60
  - “Removing access authorities” on page 60

Steps for installing and configuring the EIM domain controller on z/OS

**Before you begin**

1. You will need LDAP skills to complete this procedure for use with the IBM Tivoli Directory Server (IBM TDS) LDAP server.
2. You will need to refer to *z/OS IBM Tivoli Directory Server Administration and Use for z/OS*.

**Rule**

The following requirements must be met for the IBM TDS LDAP server, LDAP must be configured to use either the TDBM or the LDBM backend.

1. First, perform the following steps to install and configure LDAP:
   a. Use the following table to decide what you first need to do.
Table 22: EIM installation and configuration overview for the IBM TDS LDAP server

<table>
<thead>
<tr>
<th>If ...</th>
<th>Then...</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>You do not have LDAP installed and configured...</td>
<td>Follow the instructions in the Administration section of z/OS IBM Tivoli Directory Server Administration and Use for z/OS to configure the TDBM or LDBM backend.</td>
<td>The schemas schema.IBM.ldif and schema.user.ldif need to be loaded.</td>
</tr>
<tr>
<td>You have LDAP installed and configured for the SDBM backend but not the TDBM or LDBM backend...</td>
<td>Follow the instructions in the Administration section of z/OS IBM Tivoli Directory Server Administration and Use for z/OS to configure the TDBM or LDBM backend.</td>
<td>The schemas schema.IBM.ldif and schema.user.ldif need to be loaded.</td>
</tr>
<tr>
<td>You have LDAP installed and configured for the TDBM or LDBM backend...</td>
<td>Go to the next step.</td>
<td>This assumes you have loaded schema.IBM.ldif and schema.user.ldif.</td>
</tr>
<tr>
<td>You plan to use RACF user IDs and passwords to bind within the EIM domain controller...</td>
<td>Follow the instructions in the Administration section of z/OS IBM Tivoli Directory Server Administration and Use for z/OS to configure the SDBM backend for EIM.</td>
<td></td>
</tr>
</tbody>
</table>

Perform the following steps for the decision you have made.

b. The LDAP server must be configured to accept the different types of bind requests. The information from worksheet Table 18 on page 41 lists the bind mechanisms required by the EIM client applications using this EIM domain controller. See z/OS IBM Tivoli Directory Server Administration and Use for z/OS for more details.

c. Start the z/OS LDAP server as described in z/OS IBM Tivoli Directory Server Administration and Use for z/OS.

d. Load the schema definitions. See z/OS IBM Tivoli Directory Server Administration and Use for z/OS for more details.

⚠️ **Attention:**

- An EIM domain must be updated using the EIM APIs or administrative applications that use the EIM APIs. IBM does not recommend using the LDAP utilities and LDAP client APIs to update information in an EIM domain.
- Do not alter the EIM schema definitions unless directed to do so by your IBM Service representative during problem diagnosing.

**Restriction:**

z/OS LDAP by default has a 511-character limit on the length of a distinguished name for an entry when the Db2-based TDBM backend is being used. If this default length is exceeded, message ITY0023 (indicating an unexpected LDAP error) is issued, indicating that the TDBM backend database needs to be rebuilt to support longer distinguished names. This error might show up when working with long identifier, registry, domain names or suffixes.

2. Consider the options you have for setting up an EIM domain that includes z/OS:

   a. Use LDAP on z/OS as the domain controller. (z/OS and non-z/OS applications could access the data.) Using the IBM TDS LDAP server, it must be configured with either the TDBM or LDBM backend.
b. Set up the z/OS LDAP server in multi-server mode. This configuration has multiple LDAP servers sharing the same TDBM or LDBM backend store, which is useful if you want to balance the work load between your LDAP servers.

c. The z/OS EIM application can access a domain controller that resides on another platform. Figure 12 on page 47 represents a basic z/OS configuration.

![Diagram of EIM configurations involving z/OS]

**Figure 12: EIM configurations involving z/OS**

### Installing and configuring EIM on z/OS

Your z/OS system programmer uses SMP/E to install EIM into an HFS directory. By default, EIM is installed in the `/usr/lpp/eim` directory, but your system programmer can determine whether to change the default for these directories.

Table 23 on page 48 lists important directories for EIM installation. Your system programmer should review the rightmost column of this table, crossing out any defaults that have changed and recording the correct directory names.

**Tip**

An EIM administrator who uses the eimadmin utility might desire that the directory for the eimadmin utility be placed in the PATH environment variable. This enables the ability to run the utility without having to specify the path when issuing the command (or changing to the `/usr/lpp/eim/bin` directory prior to issuing the command). The PATH environment variable can be modified to include the EIM programs directory by issuing the following command from a shell prompt:

```
export PATH=$PATH:/usr/lpp/eim/bin
```

This adds the EIM programs directory to the end of the list of directories to search for programs. Add the export command to a user’s `.profile` file so that each time the user enters a shell, the PATH is updated.

<td></td>
</tr>
</tbody>
</table>

Configuring z/OS to participate in an EIM domain

This topic provides information on using RACF commands to configure z/OS to participate in an enterprise identity mapping (EIM) domain.

Servers that use an EIM domain require the name and location of the EIM domain and the appropriate credentials to bind to the LDAP directory service containing the EIM domain. The EIM domain name, its URL, bind distinguished name, and bind password can be stored in RACF profiles.

You have a couple of options to choose from when setting up the RACF profiles for EIM. The simplest is to have all servers use the same EIM domain so that you only have to set up the IRR.PROXY.DEFAULTS profile in the FACILITY class. For example:

```
RDEFINE FACILITY IRR.PROXY.DEFAULTS
PROXY(LDAPHOST(hostname) BINDDN(binddn) BINDPW(bindpw))
EIM.DOMAIN(DOMAINNAME) OPTIONS(ENABLE)
```

OPTIONS(ENABLE) is the default value.
If a server has to reference an EIM domain other than the system default, then the user ID associated with the application can be defined with the EIM domain. First, define the domain in the LDAPBIND class and then update the user profile by issuing the following commands:

```plaintext
RDEFINE LDAPBIND eim-domain
  PROXY(LDAPHOST(hostname) BINDDN(binddn) BINDPW(bindpw))
  EIM(DOMAINDN(domaindn) OPTIONS(ENABLE))
  ADDUSER ASERVER EIM(LDAPPROF(eim-domain))
```

When the server establishes a connection with an EIM domain using EIM services, the EIM services will look for the domain distinguished name, bind distinguished name, and bind password in the following order:

1. Input parameters to the EIM service.
2. The LDAPBIND profile named in the EIM segment of the caller's USER profile.
3. IRR.PROXY.DEFAULTS profile in the FACILITY class.

EIM services require a host name, bind distinguished name, bind password, and domain distinguished name before they can establish a connection with an EIM domain. The services return a configuration error if some, but not all, of the required values are provided in the input parameters, the LDAPBIND profile, or the IRR.PROXY.DEFAULTS profile.

You can temporarily disable a server or system from using the configured EIM domain without deleting the EIM information from the RACF profiles. This option can be used when you want to stop the system or server from establishing new connections with the EIM domain. When an EIM domain is disabled, existing connections to the domain are allowed to complete their work. If an EIM service is attempting to establish a connection with a domain and the domain is disabled via a RACF profile, the EIM does not look further for a domain that is enabled.

To disable a server from using the configured EIM domain, issue:

```plaintext
RALTER LDAPBIND eim-domain EIM(OPTIONS(DISABLE))
```

To disable the use of the system-wide default EIM domain, issue:

```plaintext
RALTER FACILITY IRR.PROXY.DEFAULTS EIM(OPTIONS(DISABLE))
```

**Defining RACF as the local EIM registry**

You can provide an application or server that uses EIM services with an installation-specific name for RACF on the local system. This name must correspond to the name given to that RACF registry in the EIM domain because the application uses the local RACF registry name when retrieving the mapping of a user ID. To define the registry name, issue the following commands to bring the name into storage for use by the application:

```plaintext
RALTER FACILITY IRR.PROXY.DEFAULTS EIM(LOCALREG(RACFSYS1))
```

The EIM administrator can provide you the name given to the local RACF registry in the EIM domain.

**Defining Kerberos or X.509 registry names**

If your EIM application or server handles Kerberos tickets or digital certificates, you can issue the following command to define default registry names for the configured EIM domain.

```plaintext
RALTER FACILITY IRR.PROXY.DEFAULTS
  EIM(KERBREGISTRY(kerberos-registry-name) X509REGISTRY(X.509-registry-name))
```

The registry names you define must correspond to the names given to the Kerberos and X.509 registries in the EIM domain because your EIM application uses them when retrieving the mapping of a user ID.
Steps for using the eimadmin utility to manage an EIM domain

Before you begin

This section provides an example of issuing the eimadmin command to perform tasks such as:

- Creating an EIM domain
- Granting administration authority
- Adding registries
- Adding enterprise identifiers
- Defining associations

You need to be familiar with this command. Refer to Chapter 9, “The eimadmin utility,” on page 111 and familiarize yourself with the eimadmin command.

Note: The eimadmin utility can manage an EIM domain in a z/OS or non-z/OS EIM domain controller. Refer to for “Planning for EIM client applications” on page 35 for more information.

You can perform the following steps to create and manage an EIM domain using the eimadmin utility.

Before you begin

- The eimadmin utility examples can be entered from the z/OS UNIX System Services shell by an EIM administrator.
- For improved readability each command option is shown on a separate line.
- In most cases you specify multiple options on a single line, separating them with one or more spaces.
- If necessary, you can use the backslash (\) continuation character to break the command into multiple lines.
- The access authority required for successful completion depends on the particular eimadmin operation you specify, and is determined by the bind credential you specify for LDAP authentication. The distinguished name that LDAP associates with the credential should be a member of one or more EIM access groups, which define access authority to EIM data. Refer to “Domain authentication methods” on page 53 for a description of supported bind methods.

To create the domain:

1. Create an EIM domain by entering a command such as the following from the z/OS shell:

   eimadmin
   -aD
   -d domainDN
   -n description
   -h ldapHost
   -b bindDN
   -w bindPassword

   The bindDN must be the distinguished name for the LDAP administrator. (The description is optional.)

   Example: The following command creates the EIM domain "My Domain":

   eimadmin
   -aD
   -d 'ibm-eimDomainName=My Domain,o=ibm,c=us'
   -n 'An EIM Domain'
   -h ldap://some.ldap.host
   -b 'cn=ldap administrator'
   -w secret

   Note: This assumes that the "o=ibm,c=us" objects are defined in the LDAP Directory. If these objects are not defined, refer to “Example for creating LDAP suffix and user objects” on page 386 for assistance in defining these objects if necessary.
2. Give an administrator EIM administrator authority to the domain by entering a command such as the following from the z/OS shell:

```
eimadmin
-aC
-d domainDN
-c ADMIN
-q accessUser
-i accessUserType
-h ldapHost
-b bindDN
-w bindPassword
```

The parameter following -c is the accessType parameter. In this situation, the value must be ADMIN. The bindDN must be the distinguished name for the LDAP administrator.

**Tip:** If you plan on dividing the administration responsibilities, repeat this command for the other administrative users.

**Example:** The following command can be issued by the LDAP administrator to give EIM administrator, "cn=eim administrator,ou=dept20,o=ibm,c=us", authority to administer the EIM domain:

```
eimadmin
-aC
-d 'ibm-eimDomainName=My Domain,o=ibm,c=us'
-c ADMIN
-q 'cn=eim administrator,ou=dept20,o=ibm,c=us'
-i DN
-h ldap://some.ldap.host
-b 'cn=ldap administrator'
-w secret
```

**Note:** This assumes that the "cn=eim administrator,ou=dept20,o=ibm,c=us" is defined in the LDAP Directory. If this object is not defined, refer to “Example for creating LDAP suffix and user objects” on page 386 for assistance in defining these objects if necessary.

3. Add registries to the EIM domain by entering a command such as the following from the z/OS shell:

```
eimadmin
-aR
-d domainDN
-r registryName
-y registryType
-n description
-h ldapHost
-b bindDN
-w bindPassword
```

**Note:** The -y parameter specifies registry type. (The description is optional.) See the -y registryType for more information.

**Examples:**

- The following command adds a RACF registry to the EIM domain named "My Domain":

```
eimadmin
-aR
-d 'ibm-eimDomainName=My Domain,o=ibm,c=us'
-r RACF
-y RACF
-n 'the RACF Registry on Pok System 1'
-h ldap://some.ldap.host
-b 'cn=eim administrator,ou=dept20,o=ibm,c=us'
-w secret
```

- The following command adds an OS/400 registry to the EIM domain named "My Domain":

```
eimadmin
-aR
-d 'ibm-eimDomainName=My Domain,o=ibm,c=us'
-r 'OS400 RCH1'
-y OS400
-n 'the OS400 Registry on Rochester System 1'
-h ldap://some.ldap.host
```
4. Add enterprise identifiers to the domain by entering a command such as the following from the z/OS shell:

```
eimadmin
  -aI
  -d domainDN
  -i identifier
  -n description
  -h ldapHost
  -b bindDN
  -w bindPassword
```

- You can add identifiers at any time after creating the domain.
- The preceding command adds a single identifier to the domain. Alternately, you can add multiple identifiers by specifying a file name as standard input to the eimadmin utility. Specifying a file name indicates using the file of identifiers as input for batch processing of multiple identifiers.

Repeat Step “4” on page 52 as needed.

The bindDN must have EIM administrator authority or EIM Identifier administrator authority.

The following command can be issued by the EIM administrator add to an EIM identifier to the domain My Domain:

```
eimadmin
  -aI
  -d 'ibm-eimDomainName=My Domain,o=ibm,c=us'
  -i 'John Adam Day'
  -h ldap://some.ldap.host
  -b 'cn=eim administrator,ou=dept20,o=ibm,c=us'
  -w secret
```

5. Create associations between registry user IDs and identifiers by entering commands from the z/OS shell (One or more of the association types, -t source, -t target, -t admin, are required on the command.):

```
eimadmin
  -aA
  -d domainDN
  -r registryName
  -u userid
  -i identifier
  -t admin
  -t source
  -t target
  -h ldapHost
  -b bindDN
  -w bindPassword
```

The following command creates associations between the user ID JD in the RACF Pok1 registry:

```
eimadmin
  -aA
  -d 'ibm-eimDomainName=My Domain,o=ibm,c=us'
  -r 'RACF Pok1' -u JD -i 'John Day' -t source -t target
  -h ldap://some.ldap.host -b 'cn=eim administrator,ou=dept20,o=ibm,c=us'
  -w secret
```

After you enter these commands, you can use the domain for lookup operations. For the preceding examples, the only user mappings available are mappings from JD to JOHNDAY and from JOHNDAY to JD.

**Note:**

a. You can create associations only after registries and identifiers are in place.
b. The command creates only two associations. Conversely, you can create multiple associations by specifying a file name as standard input to the eimadmin command. Specifying a file name indicates using a file of associations as input for batch processing of multiple associations.

Repeat Step “5” on page 52 as needed.

6. Give users lookup access to the EIM domain.

```bash
eimadmin -aC -d domainDN -c MAPPING -q accessUser -f DN -h ldapHost -b bindDN -w bindPassword
```

The `eimadmin` utility allows you to grant access one user at a time or a list of users can be provided in a file using the following command:

```bash
eimadmin -aC -d domainDN -c MAPPING -h ldapHost -b bindDN -w bindPassword <input-fileName
```

The file must contain a label line following by at least one user name. For example, a bind distinguished name, and the type of the user name.

```plaintext
CU cn=John Day,c=us ;CS DN ;
```

The following command can be issued by the EIM administrator add to give the end user John Day mapping (lookup) authority to the domain My Domain:

```bash
eimadmin -aC -d 'ibm-eimDomainName=My Domain,o=ibm,c=us' -c MAPPING -q 'cn=John Day,c=us' -h ldap://some.ldap.host -b 'cn=eim administrator,ou=dept20,o=ibm,c=us' -w secret
```

### Domain authentication methods

Authentication occurs when an EIM application connects (binds) to the EIM domain controller. z/OS EIM supports the following three authentication methods recognized by LDAP:

- Simple (with or without CRAM-MD5 password protection)
- Digital certificate
- Kerberos

Your LDAP server configuration and security requirements determine which method you choose. The examples in this section illustrate how you can use these methods with the eimadmin utility.

This information explains how the bind credentials specified correspond to the distinguished name that LDAP uses for access checking. Your access to EIM data is determined by the authority groups of which the distinguished name is a member. The exception is the distinguished name for the LDAP administrator that has unrestricted access.
Using simple binds

A distinguished name and password are sufficient credentials for a SIMPLE eimadmin connect type.

```
eimadmin
-1D
-d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
-h ldap://some.ldap.host
-S SIMPLE
-b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
-w secret
```

**Note:** Unless an SSL session has been established, the password is sent over the network in plain text, making this method the least secure. The distinguished name that you specify is the one LDAP uses for access checking.

Using CRAM-MD5 password protection

You can use CRAM-MD5 for simple authentication without sending the bind password over the network in plain text, provided both client and server support the method. In the utility command, specify the connect type CRAM-MD5 to indicate simple authentication with password protection.

```
eimadmin
-1D
-d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
-h ldap://some.ldap.host
-S CRAM-MD5
-b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
-w secret
```

Using digital certificates

To bind using a digital certificate, specify the EXTERNAL connect type on the eimadmin command. Ensure the host name identifies a secure host:port value prefixed with ldaps://.

**Rules**

- You must also specify the name of either a key database file or RACF key ring that contains your client certificate.
- You must specify the label for that certificate if it is not the defined default.
- If you specify a key database file but not its password, the utility prompts you for it.

```
eimadmin
-1D
-d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
-h ldaps://secure.ldap.host
-S EXTERNAL
-K client.kdb
-P clientpw
-N eimadmincert
```

**Note:** LDAP uses the client certificate’s subject distinguished name for access checking.

Using Kerberos

To bind using a Kerberos identity, specify connect type GSSAPI on the eimadmin command. No other credential information is required, but the default Kerberos credential must have been established through a service such as kinit prior to entering the command.

```
kinit eimadministrator@realm.com
eimadmin
-1D
-d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
-h ldap://some.ldap.host
-S GSSAPI
```
For access checking, LDAP considers a distinguished name formed by prefixing the Kerberos principal name with "ibm-kgn=" or distinguished names located through special mapping or searches. See z/OS IBM Tivoli Directory Server Administration and Use for z/OS for more information.

Using Secure Sockets Layer (SSL)

You can establish an SSL connection along with any of the supported authentication types if your domain controller is configured as a secure host enabled for server authentication.

A secure host is required for EXTERNAL connect.

The strength of SSL is that data transferred over the connection is encrypted, including the password for a SIMPLE bind. The eimadmin utility recognizes the need for an SSL connection when you specify an LDAP host name prefixed ldaps://. It then requires that you specify a RACF key ring, or a key database file and its password.

Installation considerations for applications

EIM applications on z/OS may require authority to RACF profiles. See “Preparing to run an EIM application” on page 73 for more information.

Configuration considerations for enabling remote services

To enable EIM to work with remote services such as identity cache and other forms of remote authorization, additional configuration steps are necessary. See “Configuring your environment to use the z/OS Identity Cache” on page 393 and “Configuring the IBM Tivoli Directory Server for remote services support” on page 399 for details on these steps.

Ongoing administration

This section explains how to perform additional administration tasks:

- Managing registries
  - Adding a system and application registry
  - Removing a registry
- Assigning an alias
  - Assigning an alias
  - Removing an alias
  - Assigning an alias to a different registry
- Adding a new user
  - Adding an identifier
  - Adding associations
- Removing a user
  - Removing associations
  - Removing an identifier
- Changing access authority
  - Adding access
  - Removing access
Managing registries

A domain typically contains multiple registries. User identities for a particular system are associated with a system registry, while a subset of identities might be associated with an application registry.

Adding a system and application registry

Create a system registry by entering the following command:

```
eimadmin -aR -r 'RACF Pok1' -y racf -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us' -h ldap://some.ldap.host -b 'cn=eimadministrator,ou=dept20,o=ibm,c=us' -w secret
```

Enter the following command to define an application registry that is dependent on a previously-defined system registry:

```
eimadmin -aR -r 'App1' -y racf -g 'RACF Pok1' -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us' -h ldap://some.ldap.host -b 'cn=eimadministrator,ou=dept20,o=ibm,c=us' -w secret
```

**Note:** Once you define an application registry, you can refer to it by name in EIM APIs and eimadmin commands without having to identify it as an application-type registry.

Listing a registry

You can list any registry using a command similar to the following:

```
eimadmin -lR -r 'App1' -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us' -h ldap://some.ldap.host -b 'cn=eimadministrator,ou=dept20,o=ibm,c=us' -w secret
```

Removing a registry

To remove a registry, issue the following command:

```
eimadmin -pR -r 'App1' -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us' -h ldap://some.ldap.host -b 'cn=eimadministrator,ou=dept20,o=ibm,c=us' -w secret
```

All associations linked to the registry are automatically deleted.

**Attention:** EIM refuses to remove a system registry if any application registries depend on it.

1. You can find the dependents that you must remove by searching for all occurrences of the system registry name in the output from the following command, which lists all registries:

```
eimadmin -lR -r '*' -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us' -h ldap://some.ldap.host
```
2. With caution, you can use the `-s rmdeps` option of eimadmin to remove dependent application registries automatically when removing the system registry.

```
eimadmin
-s rmdeps
-pR
-r 'RACF Pok1'
-d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
-h ldap://some.ldap.host
-b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
-w secret
```

Working with registry aliases

You can define alias names to facilitate registry administration. By establishing aliases that applications use to look up actual registry names, you can make non-disruptive registry changes by managing alias assignments.

**Rule**

When defining or referencing a registry alias, you must specify an associated registry type. You can use one of the suggested types (refer to “eimChangeRegistryAlias” on page 203) or invent your own.

**Assigning an alias**

Enter the following command to assign an alias name to an existing registry:

```
eimadmin
-mR
-r 'RACF Test Pok1'
-x 'z/OS' -z 'RACF'
-d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
-h ldap://some.ldap.host
-b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
-w secret
```

This example defines the alias 'z/OS' (of type 'RACF') for registry 'RACF Test Pok1'.

**Listing an alias**

You can list the registry and its aliases using the following command:

```
eimadmin
-lR
-r 'RACF Test Pok1'
-d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
-h ldap://some.ldap.host
-b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
-w secret
```

**Removing an alias**

You can delete an alias for a registry using the following command:

```
eimadmin
-eR
-r 'RACF Test Pok1'
-x 'z/OS' -z 'RACF'
-d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
-h ldap://some.ldap.host
-b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
-w secret
```

This example removes the alias 'z/OS' (of type 'RACF') for registry 'RACF Test Pok1'.
Assigning an alias name to a different registry

To assign an alias name to a different registry, add the alias name and type to the registry attributes as shown in the example for adding an alias name to a registry above.

Multiple registries can have the same registry alias values. However, if you want the alias to map to a single registry, you must remove that alias from registries in which it was previously defined.

Enter the following two commands to reassign alias 'z/OS' from registry 'RACF Test Pok1' to registry 'RACF Pok1':

```
eimadmin
    -mR
    -x 'RACF Pok1'
    -x 'z/OS' -z 'RACF'
    -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
    -h ldap://some.ldap.host
    -b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
    -w secret

eimadmin
    -eR
    -x 'RACF Test Pok1'
    -x 'z/OS' -z 'RACF'
    -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
    -h ldap://some.ldap.host
    -b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
    -w secret
```

Adding a new user

You can create a new EIM identifier to represent a new person entering your enterprise. As the person is given access to each system or application through its user registry, you can define an EIM association between the EIM identifier and the corresponding registry defined in EIM.

Adding an identifier

When you create a new EIM identifier, it is assigned a name that is unique within the domain.

The eimadmin utility requires that you specify a unique name (unlike the eimAddIdentifier API option that generates a unique name for you).

You can assign an alternate name, or alias, to multiple identifiers. This non-unique name can be used to further describe the represented individual or to serve as an alternate identifier for lookup operations.

Enter the following command to add a new identifier 'John S. Day' with two aliases:

```
eimadmin
    -aI
    -i 'John S. Day'
    -j '654321'
    -j 'Contractor'
    -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
    -h ldap://some.ldap.host
    -b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
    -w secret
```

You can list the new identifier using the unique name.

The utility returns one entry only.

```
eimadmin
    -lI
    -i 'John S. Day'
    -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
    -h ldap://some.ldap.host
    -b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
    -w secret
```

You can also list the new identifier using an alias name.
The utility returns all entries having 'Contractor' defined as an alternate name.

```
eimadmin
  -II
  -j 'Contractor'
  -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
  -h ldap://some.ldap.host
  -b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
  -w secret
```

**Adding associations**

You can register the system and application user IDs assigned to the individual by defining EIM associations between the identifier and the corresponding registries.

Enter the following command to create source and target associations for user ID 'JD' in registry 'RACF Pok1':

```
eimadmin
  -aA
  -i 'John S. Day'
  -r 'RACF Pok1'
  -u 'JD'
  -t source
  -t target
  -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
  -h ldap://some.ldap.host
  -b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
  -w secret
```

**Listing associations**

Enter the following command to list all associations for 'John S. Day':

```
eimadmin
  -LA
  -i 'John S. Day'
  -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
  -h ldap://some.ldap.host
  -b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
  -w secret
```

**Removing a user**

To completely erase a person's identity from your EIM domain, remove the identifier.

If you only need to reflect the deletion of a user ID from a registry, simply remove the corresponding EIM associations.

**Removing associations**

Enter the following command to remove the source and target associations for user ID 'JD' in registry 'RACF Pok1':

```
eimadmin
  -pA
  -i 'John S. Day'
  -r 'RACF Pok1'
  -u 'JD'
  -t source
  -t target
  -d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
  -h ldap://some.ldap.host
  -b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
  -w secret
```
Removing an identifier

Enter the following command to remove an identifier and its associations, including identifier aliases:

```bash
eimadmin
-pI
-1 'John S. Day'
-d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
-h ldap://some.ldap.host
-b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
-w secret
```

Changing access authority

A user is permitted to perform EIM administrative or lookup operations based on the authority groups containing the user's LDAP distinguished name (DN). The user's DN is determined by the credentials authenticated when connecting to LDAP.

Suppose a user has registry administrator authority over a specific registry and your task is to switch the user's authority to a different registry. You can accomplish this task in two steps:

1. Adding the user to the new registry administrator group
2. Removing the user from the prior group

Adding access authorities

Enter the following command to add user DN 'cn=Reggie King,ou=dept20,o=ibm,c=us' to the registry administration group for 'RACF Pok1':

```bash
eimadmin
-aC
-q 'cn=Reggie King,ou=dept20,o=ibm,c=us'
-f DN
-c registry
-r 'RACF Pok1'
-d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
-h ldap://some.ldap.host
-b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
-w secret
```

Listing access authorities

Enter the following command to list all EIM access authorities for the user:

```bash
eimadmin
-lC
-q 'cn=Reggie King,ou=dept20,o=ibm,c=us'
-f DN
-d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
-h ldap://some.ldap.host
-b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
-w secret
```

Removing access authorities

Enter the following command to remove the user from the prior registry administration group for 'RACF Test Pok1':

```bash
eimadmin
-pC
-q 'cn=Reggie King,ou=dept20,o=ibm,c=us'
-f DN
-c registry
-r 'RACF Test Pok1'
-d 'ibm-eimDomainName=MyDomain,o=ibm,c=us'
-h ldap://some.ldap.host
-b 'cn=eimadministrator,ou=dept20,o=ibm,c=us'
-w secret
```
Chapter 6. Using RACF commands to set up and tailor EIM

An EIM administration application creating, deleting, or changing descriptive information about a domain must provide domain name and bind information. This chapter explores:

- “Setting up default domain LDAP URL and binding information” on page 62
  - “Storing LDAP binding information in a profile” on page 62
    - “Adding EIM domain and bind information for servers or administrative users” on page 63
    - “Adding a system default using the IRR.EIM.DEFAULTS profile” on page 64
    - “Adding a system default using the IRR.PROXY.DEFAULTS profile” on page 64
- “Optionally setting up a registry name for your local RACF registry” on page 64
  - “Steps for setting up lookups that do not need a registry name” on page 64
- “Ongoing RACF administration” on page 65
  - “Disabling use of an EIM domain” on page 65
  - “Using output from the RACF database unload utility and eimadmin to prime your EIM domain with information” on page 65

Using RACF for EIM domain access

The RACF administrator can use RACF commands to do the following:

- Add an EIM domain name and bind information for system-wide use
- Add an EIM domain name and bind information for use by a server
- Add an EIM domain name and bind information for use by an administrative user
- Assign a name to the local RACF registry for use by a lookup application

Tip

Issuing these commands is optional. However, setting up your system this way can eliminate the need for individual applications to handle EIM domain and bind information.

The default domain and bind information can be specified in one of three places:

1. The user ID the application runs under has the name of an LDAPBIND class profile in its USER profile
2. The IRR.EIM.DEFAULTS profile in the LDAPBIND class
3. The IRR.PROXY.DEFAULTS profile in the FACILITY class

These RACF profiles can be set up in such a way as to control the access the application has to the EIM domain:

- New connections with an EIM domain can be enabled or disabled by using keywords on the RDEFINE or RALTER commands.
- Bind credentials can be specific to the server or administrator who uses them.

The EIM APIs try to retrieve the information from a profile if the application does not explicitly supply the information to the EIM APIs using parameters. Applications or other services that use EIM can instruct their callers to define a profile in the LDAPBIND class profile.
Setting up default domain LDAP URL and binding information

Servers that use an EIM domain require the name and location of the EIM domain and the appropriate credentials to bind to the LDAP directory service containing the EIM domain. You can store the EIM domain name, its URL, bind distinguished name, and bind password in RACF profiles. (See Table 24 on page 62 for the ways a security administrator can set up profiles.)

This section explores:

- “Storing LDAP binding information in a profile” on page 62
- “Adding EIM domain and bind information for servers or administrative users” on page 63
- “Adding a system default using the IRR.EIM.DEFAULTS profile” on page 64
- “Adding a system default using the IRR.PROXY.DEFAULTS profile” on page 64

Storing LDAP binding information in a profile

Before you begin

- Use the following decision table to determine which profile to use:

<table>
<thead>
<tr>
<th>If …</th>
<th>Then …</th>
</tr>
</thead>
<tbody>
<tr>
<td>The EIM domain is in the default system LDAP directory …</td>
<td>Set up the IRR.PROXY.DEFAULTS profile in the FACILITY class. (This is the simplest way to set up a profile.)</td>
</tr>
<tr>
<td>A server needs to reference an EIM domain that is not in the system default LDAP directory … (This could be because the IRR.PROXY.DEFAULTS profile has different bind information than the application using the EIM domain requires.)</td>
<td>Set up a profile in the LDAPBIND class. Add the name of the LDAPBIND class profile to the user profile used by the application.</td>
</tr>
</tbody>
</table>

- **Tip:** You need to know certain information to use as parameters in RACF commands. Refer to the z/OS Security Server RACF Command Language Reference for more information. Fill in the missing (Value column) information in the following table:

<table>
<thead>

</tr>
<tr>
<td>JOESDOMAIN</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** This profile can be a profile defined in the LDAP bind class, the IRR.EIM.DEFAULTS profile in the LDAPBIND class, or the IRR.PROXY.DEFAULTS profile in the FACILITY class.

---

**Adding EIM domain and bind information for servers or administrative users**

To create a profile for LDAP binding information:

1. Perform the following steps if you are creating a profile in the LDAPBIND class:
   a. To define the domain in the LDAPBIND class, enter:

   ```
   RDEFINE LDAPBIND racfProfileName
   EIM(DOMAINDN(domainDN))
   PROXY(LDAPHOST(ldapHost)
   BINDDN(bindDN) BINDPW(bindPasswd))
   ```

   **Note:**

   1) OPTIONS(ENABLE) is the default value.

   b. To update the user profile:

   ```
   ADDUSER ASERVER EIM(LDAPROF(racfProfileName))
   ```

---

Using RACF commands to set up and tailor EIM 63
Adding a system default using the IRR.EIM.DEFAULTS profile

1. If you are using the IRR.EIM.DEFAULTS profile in the LDAPBIND class, enter:

   ```
   RDEFINE LDAPBIND IRR.EIM.DEFAULTS
   PROXY(LDAPHOST(ldapHost))
   BINDDN(bindDN) BINDPW(bindPasswd))
   EIM(DOMAINDN(domainDN))
   ```

   **Note:** OPTIONS(ENABLE) is the default value.

Adding a system default using the IRR.PROXY.DEFAULTS profile

If no LDAPBIND class profile is associated with the caller's user profile, the EIM services look for the EIM domain's LDAP URL and binding information in the IRR.EIM.DEFAULTS profile in the LDAPBIND class followed by the IRR.PROXY.DEFAULTS profile in the FACILITY class. For example, the following command sets up the binding information in the IRR.PROXY.DEFAULTS profile in the FACILITY class:

```
RDEFINE FACILITY IRR.PROXY.DEFAULTS
PROXY(LDAPHOST(LDAP://SOME.BIG.HOST:389)
BINDDN('cn=Joes Admin,o=ibm,c=us') BINDPW(secret))
EIM(DOMAINDN('ibm-eimDomainName=Joes Domain,o=ibm,c=us'))
```

In this case, the domain's LDAP URL is:

- **LDAP://SOME.BIG.HOST:389/ibm-eimDomainName=Joes Domain,o=ibm,c=us**

Optionally setting up a registry name for your local RACF registry

Many of the EIM APIs require the name of a registry. For example, if you are adding a registry to an EIM domain, you should know the name of the new registry. However, you can use the lookup APIs (such as eimGetTargetFromSource, eimGetIdentifierFromSource, and eimGetAssociatedIdentifiers) to convert:

1. A user ID to its equivalent RACF user ID
2. A local RACF user ID to an enterprise identifier

For such applications, you can eliminate the requirement for providing the RACF registry name or its alias on the local system. You do this by giving a name to the local RACF registry.

Steps for setting up lookups that do not need a registry name

You need to know the registry name before you begin.

<table>
<thead>
<tr>
<th>Information needed</th>
<th>Where to get it</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>registryName — The name of the RACF registry. Example: Registry on POK System</td>
<td>EIM administrator</td>
<td></td>
</tr>
</tbody>
</table>

Perform the following to set up EIM so that you do not need a registry name on every lookup. To define the local registry, enter the following RACF command in which `registryName` is the name of the local registry:

```
RDEFINE FACILITY IRR.PROXY.DEFAULTS EIM(LOCALREGISTRY(registryName))
```

**Note:** EIM does not look for the registry name in an LDAPBIND class profile.
You can also configure the system with a kerberos registry name and an X.509 registry name. Issue the following commands to define default kerberos and X.509 registries for the configured EIM domain:

```
RALTER FACILITY IRR.PROXY.DEFAULTS EIM(KERBREGISTRY(registry name) X509REGISTRY(registry name))
```

This access can be removed with the following command:

```
RALTER FACILITY IRR.PROXY.DEFAULTS EIM(NOKERBREGISTRY NOX509REGISTRY)
```

Note that these registry names need to be defined in the configured EIM domain.

For more information on defining a registry name, refer to “EIM registry definition” on page 11.

**Ongoing RACF administration**

You might need to perform the following tasks as part of ongoing RACF administration:

- “Disabling use of an EIM domain” on page 65
- “Using output from the RACF database unload utility and eimadmin to prime your EIM domain with information” on page 65

### Disabling use of an EIM domain

You might need to temporarily disable use of a RACF profile with a configured EIM domain or a system-wide default EIM domain. You might want to do this if the EIM information in a domain has been compromised or a security administrator wants to stop the system or server from establishing new connections with the EIM domain. You can use RACF commands to disable a domain without deleting EIM information from the RACF profiles. When an EIM domain is disabled through a RACF profile, existing connections to the domain complete their work. However, if an EIM service is trying to establish a connection with such a domain, the EIM service does not continue to look for an enabled domain.

#### Steps for disabling use of an EIM domain

Perform the following steps to disable a server from using the configured EIM domain (This applies only to a server that has an ldapbind class profile specified for its user ID):

1. If you want to disable a server (rather than a system) from using a configured EIM domain, enter the following command:

```
RALTER LDAPBIND ldapbind_profile EIM(OPTIONS(DISABLE))
```

**Note:** No change is required to the user profile.

#### Tip

To disable a system-wide default EIM domain (rather than a server) that default profiles use, enter one of the following commands:

```
RALTER FACILITY IRR.PROXY.DEFAULTS EIM(OPTIONS(DISABLE))
```

```
RALTER LDAPBIND IRR.EIM.DEFAULTS EIM(OPTIONS(DISABLE))
```

### Using output from the RACF database unload utility and eimadmin to prime your EIM domain with information

You can start to put EIM information (identifiers, RACF user IDs, and associations) into your EIM domain by using output from DBUNLOAD and eimadmin.
For large installations, priming the EIM domain with identifiers and associations can involve a lot of work. To make the task of getting started with EIM easier, the eimadmin utility accepts as input a file containing a list of identifiers and associations.

The section explores the steps for setting up an EIM domain based on user information contained in a RACF database. The initial assumptions are that the EIM domain, World Wide Domain, has been created and a SAF system registry, SAF user IDs, is defined in the domain. The ldap host name for the domain is ldap://some.big.host. The EIM administrator uses the bind distinguished name of cn=EIM Admin, o=My Company, c=US and the password is secret. The EIM administrator bind distinguished name has been given EIM administrator authority and can perform all of the following steps. A user with other types of EIM authority can perform a subset of the following steps:

- EIM identifier administrator authority only works with identifiers and source and target associations
- EIM registries administrator authority only works with target associations
- EIM registry-specific administrator authority for the SAF registry only works with target associations in the SAF registry

1. Request from your RACF security administrator a file containing a copy of the user profiles in the RACF database. The RACF security administrator can:
   a. Run the database unload utility (IRRDBU00) to create the sequential file
   b. Run the file through a sort program, such as DFSORT or DFSORT ICETOOL to extract just the user profiles and desired fields. The User Basic Data Record (0200) contains the user ID and the programmer name. In this example, the programmer name is used for the EIM identifier.

The DFSORT ICETOOL Report format has a 1-4 character name (for example, EIM). It contains the ICETOOL statements that control report format and record summary information, such as SORT, COPY, DISPLAY, and OCCURS statements. An example of a report format which can be used to extract RACF user IDs and the programmer names associated with the user IDs follows:

Example:

```
**********************************************************************
* Name: EIM                                                          *
*                                                                    *
* Find all user IDs in the RACF database and their name              *
**********************************************************************
COPY    FROM(DBUDATA) TO(TEMP0001) USING(RACF)
OCCURS  FROM(TEMP0001) LIST(PRINT) -
     TITLE('user IDs and Names') -
     ON(10,8,CH) HEADER('USER ID') -
     ON(79,20,CH) HEADER('Name')
```

The record selection criteria is as follows:

- The name of the member containing the record selection criteria is the report member name followed by CNTL (such as EIMCNTL).
- Record selection is performed using DFSORT control statements, such as SORT and INCLUDE.
- The SORT command is used to select and sort records.
- The INCLUDE command is used to specify conditions required for records to appear in the report.

The following is an example of the record selection criteria that could be used. In this report, we are including only User Base records (record type 0200) which have the RACF user ID and the programmer name. The selection criteria allows records for the special RACF user IDs, irrcerta, irrmulti, and irrsitec, to remain undisclosed in the final report.

```
SORT    FIELDS=(10,8,CH,A)
INCLUDE COND=(5,4,CH, EQ, C’0200’,AND,
     (10,8,CH,NE,C’irrcerta’,AND,
     10,8,CH,NE,C’irrmulti’,AND,
     10,8,CH,NE,C’irrsitec’))
     10,7,CH,NE,C’IBMUSER’,AND,
OPTION  VLSHRT
```
To use the RACFICE procedure to generate the report:

```sql
//jobname JOB Job card...
//        SET DBUDATA=USER01.TEST.IRRDBU00
//stepname EXEC RACFICE,REPORT=EIM
```

Result - The output from the utility looks like this:

<table>
<thead>
<tr>
<th>User ID</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANN</td>
<td>ANN J. AUSTIN</td>
</tr>
<tr>
<td>CHRIS</td>
<td>CHRISTINE IRVING</td>

</tr>
<tr>
<td>WILLY</td>
<td>WILLIAM TROTSKY</td>
</tr>
</tbody>
</table>

Tip:

- z/OS Security Server RACF Security Administrator's Guide contains instructions on how to run the database unload utility and use the sort programs.

2. When you receive the report from the security administrator, you should move it to a file in the hierarchical file system (HFS).
3. Add a eimadmin utility "label line" to the file containing user profiles. You can use any one of the editors available from the OMVS shell (such as OEDIT).

The following is an example of the updated file, racfUsers.txt with a label line added and the DFSORT column headers commented out.

Tip:

Any user IDs that should not go into the EIM domain, such as user IDs belonging to servers, can also be commented out.

```sql
#User ID     Name              
#-----------   -------------------
UN           ; IU                 
ANN          ANN J. AUSTIN     
CHRIS        CHRISTINE IRVING  
DENICE       DENICE GARDNER    
DIANA        DIANA MACMILLIAN  
ERIC         ERIC D. ADAMS     
JAY          JASON SWIFT       
MAURA        MAURA FISHER      
OMAR         OMAR ZACHARY      
PEGGY        PEGGY B. WOLF     
RANDY        RANDY BRAUTIGAN   
RICH         RICH CLANCY       
ROSS         ROSS SIMPSON      
SCOTT        SCOTT SMYTHE      
SHOZAB       SHOZAB SYED       
SHRUTI       SHRUTI MODI       
TERRY        TERRY HAMMER      
TRACY        TRACY ROWLINGS    
VIVIAN       VIVIAN BRONTE     
WILLY        WILLIAM TROTSKY   
```
4. Add identifiers and list the results using the eimadmin shell command:

```bash
eimadmin
-aI
-d "ibm-eimDomainName=World Wide Domain,o=My Company,c=US"
-h ldap://some.big.host
-b "cn=EIM Admin,o=My Company,c=US"
-w secret <racfUsers.txt
```

5. To list the identifiers added in the preceding step, issue:

```bash
eimadmin
-lI
-d "ibm-eimDomainName=World Wide Domain,o=My Company,c=US"
-h ldap://some.big.host
-b "cn=EIM Admin,o=My Company,c=US"
-w secret <racfUsers.txt
```

6. Create source and target associations between the identifiers and the user IDs in RACF. Because the file `racfUsers.txt` contains a label line that identifies user IDs as well as unique identifier names, it can be used to create associations:

```bash
eimadmin
-aA
-t source
-t target
-r "SAF user IDs"
-d "ibm-eimDomainName=World Wide Domain,o=My Company,c=US"
-h ldap://some.big.host
-b "cn=EIM Admin,o=My Company,c=US"
-w secret <racfUsers.txt
```

7. To list the associations added in the preceding step:

```bash
 eimadmin
 -lA
 -d "ibm-eimDomainName=World Wide Domain,o=My Company,c=US"
 -h ldap://some.big.host
 -b "cn=EIM Admin,o=My Company,c=US"
 -w secret <racfUsers.txt
```

8. The following eimadmin commands can be used to give EIM Mapping Operations authority to each of the users (identified in the file `racfUsersDNs.txt`):

```bash
 eimadmin
 -aC
 -c MAPPING
 -d "ibm-eimDomainName=World Wide Domain,o=My Company,c=US"
 -f DN
 -h ldap://some.big.host
 -b "cn=EIM Admin,o=My Company,c=US"
 -w secret <racfUsersDNs.txt
```

To list the accesses that have been granted, issue:

```bash
 eimadmin
 -lC
 -c MAPPING
 -d "ibm-eimDomainName=World Wide Domain,o=My Company,c=US"
 -h ldap://some.big.host
 -b "cn=EIM Admin,o=My Company,c=US"
 -w secret <racfUsersDNs.txt
```

Tip:

At a minimum, a user who is looking for a mapping in the EIM domain needs to have EIM mapping operations authority. In most cases, the application has one set of credentials for connect with an EIM domain, and those credentials are shared by all users. However, if individual access is needed, then a bind distinguished name needs to be defined for each of the users and given EIM mapping operations authority.
Suppose the file racfUsersDNs.txt contains this list of bind distinguished names that were defined to the LDAP server containing the EIM domain controller and an eimadmin label line:

```
CU                                      ;
  cn=Ann J. Austin,o=My Company,c=US
  cn=Chrisine Irving,o=My Company,c=US
  cn=Denice Gardener,o=My Company,c=US
  cn=Diana MacMillian,o=My Company,c=US
  cn=Eric D. Adams,o=My Company,c=US
  cn=Jason Swift,o=My Company,c=US
  cn=Maura Fisher,o=My Company,c=US
  cn=Omar Zachary,o=My Company,c=US
  cn=Peggy B. Wolf,o=My Company,c=US
  cn=Randy Brautigan,o=My Company,c=US
  cn=Rich Clancy,o=My Company,c=US
  cn=Ross Simpson,o=My Company,c=US
  cn=Scott Smythe,o=My Company,c=US
  cn=Shozab Syed,o=My Company,c=US
  cn=Shzuti Modi,o=My Company,c=US
  cn=Terry Hammer,o=My Company,c=US
  cn=Tracy Rowlings,o=My Company,c=US
  cn=Vivian Bronte,o=My Company,c=US
  cn=William Trotsky,o=My Company,c=US
```
Ongoing RACF administration
Chapter 7. Developing applications

The z/OS UNIX programmer codes customer EIM lookups and administrative applications, integrating calls to the EIM APIs within these applications. The EIM APIs are implemented as "C" programming interfaces.

This chapter explores:

- “Writing EIM applications” on page 71
  - “Default registry names ” on page 71
  - “Defining private user registry types in EIM” on page 71
    - “Define a private user registry type in EIM” on page 71
- “Building an EIM application” on page 72
  - “C/C++ Compile considerations” on page 73
  - “C/C++ Link-edit considerations” on page 73
- “Preparing to run an EIM application” on page 73
- “APIs for retrieving the LDAP URL and binding information” on page 75
- “Determining why a mapping is not returned” on page 76

Writing EIM applications

Default registry names

Many of the EIM APIs require the specification of the name of a registry. For example, if you are adding a registry to an EIM domain, you should know the name of the new registry being used. However, you might use the lookup APIs (such as eimGetTargetFromSource, eimGetTargetFromIdentifier, and eimGetAssociatedIdentifiers) to convert:

- A user ID to its equivalent RACF user ID
- A local RACF user ID to an enterprise identifier

**Tip:** For such applications, you can eliminate the requirement for providing the RACF registry name or its alias on the local system. This is done by storing a name for the local RACF registry in the IRR.PROXY.DEFAULTS profile in the FACILITY class.

Defining private user registry types in EIM

Define a private user registry type in EIM

To define a user registry type that EIM is not predefined to recognize, you must specify the registry type in the form of ObjectIdentifier-normalization, where ObjectIdentifier is a dotted decimal object identifier (OID), such as 1.2.3.4.5.6.7, and normalization is either the value caseExact or the value caseIgnore.

If you need a private OID for use only within your enterprise, you can pick any arbitrary number not already in use. However, private OIDs that you want to use outside your enterprise must be obtained from legitimate OID registration authorities. Doing so ensures that you create and use unique OIDs which helps you avoid potential OID conflicts with OIDs created by other organizations.

There are two ways of obtaining OIDs:

1. Registering your OIDs with an authority is a good choice, for example, when you need a small number of fixed OIDs to represent information. For example, these OIDs might represent certificate policies for users in your enterprise.
2. Obtaining an arc assignment, which is a dotted decimal object identifier range assignment, is a good choice if you need a large number of OIDs, or if your OID assignments are subject to change. The arc assignment consists of the beginning dotted decimal numbers from which you must base your ObjectIdentifier. For example, the arc assignment could be 1.2.3.4.5.. You could then create OIDs by adding to this basic arc. For example, you could create OIDs in the form 1.2.3.4.5.x.x.x)

**Tip:**
You can learn more about registering your OIDs with a registration authority by reviewing these Internet resources:

- ANSI is the registration authority for the United States for organization names under the global registration process established by ISO and ITU. For a fact sheet with links to an application form, see American National Standards Institute (ANSI) (www.ansi.org).

**Note:** The ANSI OID arc for organizations is 2.16.840.1. ANSI charges a fee for OID arc assignments. It takes approximately two weeks to receive the assigned OID arc from ANSI. ANSI will assign a number (NEWNUM), creating a new OID arc: 2.16.840.1. NEWNUM.

- In most countries or regions, the national standards association maintains an OID registry. As with the ANSI arc, these are generally arcs assigned under the OID 2.16. It might take some investigation to find the OID authority for a particular country or region. To find the addresses for ISO national member bodies, see International Organization for Standardization (ISO) (www.iso.org). The information includes a postal address and electronic mail, and in many cases a Web site is specified as well.

- Another possible starting point is the International Register of ISO DCC Network Service Access Point (NSAP) schemes. To find the registry for schemes, see Federation of the Electronics Industry (FEI) (www.fei.org.uk). This Web site currently lists contact information for thirteen naming authorities, some of which also assign OIDs.

- The Internet Assigned Numbers Authority (IANA) assigns private enterprise numbers, which are OIDs, in the arc 1.3.6.1.4.1. IANA has assigned arcs to over 7,500 companies to date. For more information, see Internet Assigned Numbers Authority (IANA) (www.iana.org), and search for "Private Enterprise Numbers". The IANA OID is free and is usually received in about one week. IANA assigns a number (NEWNUM), so the new OID arc will be 1.3.6.1.4.1.NEWNUM.

- The U.S. Federal Government maintains the Computer Security Objects Registry (CSOR). The CSOR is the naming authority for the arc 2.16.840.1.101.3, and is currently registering objects for security labels, cryptographic algorithms, and certificate policies. The certificate policy OIDs are defined in the arc 2.16.840.1.101.3.2.1. The CSOR provides policy OIDs to agencies of the United States Federal Government. For more information about the CSOR, see Computer Security Resource Center (CSRC) (csrc.nist.gov).

For more information on OIDs for certificate policies, see Computer Security Resource Center (CSRC) (csrc.nist.gov).

### Building an EIM application

Any user of an EIM application (including eimadmin) needs a z/OS UNIX System Services UID and GID assigned to them. See z/OS UNIX System Services Planning for details on how to do this.

This section explores:

- “C/C++ Compile considerations” on page 73
- “C/C++ Link-edit considerations” on page 73

**Note:** The EIM programming interface is provided in a set of C/C++ functions in the EIM DLL and a pair of Java jar files. The DLL is loaded at program run time so that calls to the functions in the interface can be made. In order to compile and link-edit a C/C++ program that uses the EIM API, use the following guidelines.
C/C++ Compile considerations

Put the following include statement in all C or C++ source files that make calls to the EIM programming interface or use EIM data structures.

#include <eim.h>

**Note:** If defaults were used during EIM installation, the eim.h file is located in the /usr/lpp/eim/include directory. The eim.h file has been symbolically linked in the /usr/include directory. If EIM was not installed in the default location, you might need to specify the directory where the compiler is to find the eim.h file with the -I parameter.

**Tip**

Specify -D_EIM_EXT on the compile of the source files that include eim.h. This ensures full support for the errno values defined for EIM and that they are proper by defined for your application's use. Additionally, the Language Environment library level must be at z/OS release 4 or higher. To set the Language Environment library level to the z/OS Version 1 Release 4 level, specify target(0x41040000).

When compiling a program that makes EIM API calls, be sure to specify the DLL option to the compiler. (-Wc,dll when using the c89/cc/c++ commands)

**Tip**

Ensure your application has POSIX(ON) specified so it can use the EIM APIs.

The values returned by the EIM APIs are standard POSIX errnos with five additions. These errnos, including the additions, can be used as input to the strerror() or perror() functions:

- EBADDATA = Data is not valid
- EUNKNOWN = Unknown system state
- ENOTSUP = Operation not supported
- EBADNAME = The object name specified is not correct
- ENOTSFAFE = The function is not allowed

Refer to “eimErr2String” on page 232 for more information.

C/C++ Link-edit considerations

**Tip**

When link-editing, be sure to specify the EIM “exports” file in the set of files to be link-edited with the program.

The EIM export file (eim.x) is located in the library directory of the EIM install directory, which is /usr/lpp/eim/lib by default. For convenience, a symbolic link to this file has been created in the /usr/lib directory. If the default directory was used during EIM installation, the export file could be specified as /usr/lib/eim.x or /usr/lpp/eim/lib/eim.x.

Preparing to run an EIM application

**Tip**

When running an EIM application, be sure that the EIM DLL is accessible by ensuring the LIBPATH environment variable includes /usr/lib. Be sure that the directory your programs are located in are in the PATH environment variable.

Since the EIM message catalogs are symbolically linked in the /usr/lib/nls/msg directories, it should not be necessary to update NLSPATH.
**Note:** previous releases of z/OS required programs that used the EIM APIs to be APF-authorized. This requirement no longer exists. This means that you must remove the APF-authorization extended attribute for each existing EIM application program (new applications you add for this release are not affected). This attribute is removed by using the `extattr –a` command.

For example `extattr –a eimprog` would remove the APF-authorization bit for the program `eimprog` in the current directory. For more information on the `extattr` command, refer to `z/OS UNIX System Services Command Reference` or `z/OS UNIX System Services Planning`.

### Accessing RACF profile checks

If your C/C++ or Java application is retrieving configuration information from RACF profiles, for example:
- the default EIM domain dn, ldap host, bind dn, and bind password
- the default registry names

then the RACF user ID of the application callers may need authority to SAF services that allow the information to be retrieved from the RACF database.

The following table lists the access requirements for the EIM APIs when they need to obtain information configuration information from a RACF profile.

<table>
<thead>
<tr>
<th>EIM C/C++ API</th>
<th>SAF Callable service used by the EIM APIs</th>
<th>Authorization requirements for the calling application.</th>
</tr>
</thead>
</table>
| eimCreateHandle, eimGetAssociatedIdentifiers eimGetTargetFromIdentifier eimGetTargetFromSource eimRetrieveConfiguration | R_GetInfo | The calling application can be running in system key or supervisor state or one of the following:
- The RACF user ID of the caller's address space has READ authority to the BPX.SERVER profile in the FACILITY class
- The current RACF user ID has READ authority to the IRR.RGETINFO.EIM profile in the FACILITY class

The FACILITY class must be active and RACLISTed before unauthorized (problem program state and keys) will be granted the authority to use this SAF service. |
| eimConnect, eimConnectToMaster | R_dcekey | The calling application can be running in system key or supervisor state or one of the following:
- The RACF user ID of the caller's address space has READ access to the BPX.SERVER profile in the FACILITY class
- The current RACF user ID has READ authority to the IRR.RDCEKEY profile in the FACILITY class

Applications that are not authorized (problem program state and keys) must be program controlled (extattr +p), the address space must be clean and the FACILITY class must be active and RACLISTed before the application will be granted authority to use this SAF service. |
Table 27: EIM API access requirements (continued)

<table>
<thead>
<tr>
<th>EIM C/C++ API</th>
<th>SAF Callable service used by the EIM APIs</th>
<th>Authorization requirements for the calling application.</th>
</tr>
</thead>
</table>
| eimSetConfigurationExt | R_GetInfo, R_admin                        | The calling application can be running in system key or supervisor state or one of the following:  
|                      |                                          | • The RACF user ID of the caller's address space has READ authority to the BPX.SERVER profile in the FACILITY class  
|                      |                                          | • The current RACF user ID has READ authority to the IRR.RGETINFO.EIM profile in the FACILITY class  
|                      |                                          | For applications that are not authorized (problem program state and keys), the current RACF user ID must satisfy the following requirements:  
|                      |                                          | • Have READ authority to the following profiles in the FACILITY class:  
|                      |                                          | – IRR.RADM.ALTUSER  
|                      |                                          | – IRR.RADM.RDEFINE  
|                      |                                          | – IRR.RADM.RALTER  
|                      |                                          | – IRR.RADM.RDELETE  
|                      |                                          | • Have authority to issue the following commands:  
|                      |                                          | – ALTUSER  
|                      |                                          | – RALTER  
|                      |                                          | – RDEFINE  
|                      |                                          | – RDELETE  
|                      |                                          | The FACILITY class must be active and RACLISTed before the application will be granted authority to use this SAF service |

**Special considerations for applications that will be shared between different releases of z/OS**

Prior to z/OS V1R7, the EIM application needed to be APF authorized. For z/OS V1R7 or later, the application should not be APF authorized. The one exception is when the application is shared between a down level system and a z/OS V1R7 or later system. The application must remain APF authorized in order for it to work on the down level system. For more details on APF authorization, see “Preparing to run an EIM application” on page 73.

**APIs for retrieving the LDAP URL and binding information**

EIM APIs, eimCreateHandle, eimConnect, and eimConnectToMaster, use SAF APIs to retrieve the domain's LDAP URL and binding information from RACF profiles when the caller does not provide them. The order of search for the domain and bind information is:

1. As input parameters on the call to the EIM API
2. In profiles as follows:
a. LDAPBIND profile named in the EIM segment of the caller’s USER profile
b. IRR.EIM.DEFAULTS profile in the LDAPBIND class
c. IRR.PROXY.DEFAULTS profile in the FACILITY class

It is reasonable for domain APIs to have access to the domain’s LDAP URL and binding information because only:

• The LDAP administrator can create a domain
• A limited number of users have the authority to change, delete or list domain information

The eimRetrieveConfiguration API can also retrieve configuration information, from a specific profile or the current system settings. For more information see “eimRetrieveConfiguration” on page 348.

**Tip**

Applications, servers, or operating systems can use other APIs (such as registry, identifier, association, access control, and lookup APIs) that should obtain the domain’s LDAP URL and binding information from a source the security administrator controls.

**Determining why a mapping is not returned**

If your application is up and running, it should be able to connect to the EIM domain controller. However, if it does not return expected results for the EIM API, the following could be happening:

• The EIM information you are trying to retrieve is not defined in the EIM domain
• The end user does not have the correct level of authority to the information

**Tip**

Some things the EIM administrator can consider for investigation:

1. List the EIM information to verify that the EIM information you are looking for is defined.
2. Verify that the user you are connecting with has the required level of authority for the API you are using.
Chapter 8. Messages

Enterprise Identity Mapping (EIM) on z/OS uses message catalogs to store error strings and messages. The error strings explain why a particular return code (or errno) is returned by an EIM API. The messages are issued by the eimadmin utility. Message catalogs makes it easier for software to provide versions of error strings and messages in languages other than English.

All of the messages in this section with the exception of the ITY4xxx messages are error strings. The error strings are in the format that is returned by a catgets() function.

An error string or message has the following format:

```
ITYnnnn  text
```

`nnnn`  
The message ID number in the message catalog.

The text of an error string might contain an XPG4 conversion specification for a substitution value. A conversion specification has the following format:

```
%n$x
```

```
%  
The start of the conversion specification

n  
The nth argument after the format-string of an fprintf, sprintf, or printf function

$  
A delimiter

x  
The kind of variable (for example, s=string)
```

More details on XPG4 conversion specifications and their use can be found in z/OS XL C/C++ Runtime Library Reference.

The error message IDs in the EIM message catalog are divided into ranges based on function:

- **ITY0xxx**  
  Error strings that an EIM API returns (across iSeries, zSeries, pSeries, and xSeries platforms)

- **ITY3xxx**  
  Identity cache error messages

- **ITY4xxx**  
  Messages that the eimadmin utility issues

- **ITY6xxx**  
  z/OS-specific error strings

The application programmer has two options for handling error strings in an EIM application:

- Retrieve the error string from the message catalog, format the error string into a message, and print the message to the screen or error log.
- Use the eimErr2String API, which retrieves the error string and formats it into a message that can be printed using one of the C or C++ printf functions. Note that this only works with EIM error messages; java error messages, such as those from identity cache, are excluded from this function.

An application that works directly with the message catalog needs to do the following:

1. Open the message catalog using the catopen function.
2. Read the error string from the message catalog using the catgets function.
3. Format the message and fill in any substitution values EIM returns by using one of the `fprintf` family of functions—`fprintf()`, `sprintf()`, `printf()`.

4. Close the message catalog using the `catclose` function

These functions require the message catalog set number and message ID, which are contained in the `EimRC` return code parameter on the EIM APIs. See the `z/OS XL C/C++ Runtime Library Reference` for details on how to use these functions.

The `eimErr2String` API simplifies the task of creating the message by performing this processing for you.

**ITY0001 Insufficient access to EIM data.**

**Explanation**
The bind distinguished name did not have sufficient authority to access the desired EIM data. LDAP returned `LDAP_INSUFFICIENT_ACCESS` to the requested operation.

**System action**
The called function fails.

**Programmer response**
Correct the error and try the service again.

**Symbolic Identifier (value)**
EIMERR_ACCESS_TYPE_INVAL (2)

**ITY0003 Access user type is not valid.**

**Explanation**
The value specified for the user access type parameter is either not a valid access type or not supported on this platform.

**System action**
The called function fails.

**Programmer response**
Check the documentation for the EIM API and verify the user access type is supported. If the user access type is not supported or an incorrect value was specified for the access type, correct the program and try the service again.

**Symbolic Identifier (value)**
EIMERR_ACCESS_USERTYPE_INVAL (3)

**ITY0004 Association type is not valid.**

**Explanation**
The value specified for the association type parameter is not a valid type of association.

**System action**
The called function fails.

**Programmer response**
Correct the error and try the service again.

**Symbolic Identifier (value)**
EIMERR_ASSOC_TYPE_INVAL (4)

**ITY0005 Attribute name is not valid.**

**Explanation**
The value specified for the association type parameter is not a valid type of association.
Explanation
The value specified for the attribute parameter is either not a valid attribute or not supported on this platform.

System action
The called function fails.

Programmer response
Check the documentation for the EIM API and verify the attribute is supported. If the attribute is not supported or an incorrect value was specified for the attribute, correct the program and try the service again.

Symbolic Identifier (value)
EIMERR_ATTR_INVAL (5)
ITY0006    Attribute not supported.

Explanation
The value specified for the handle attribute is either not a valid attribute or not supported on this platform.

System action
The called function fails.

Programmer response
Check the documentation for the EIM API and verify the attribute is supported. If the attribute is not supported or an incorrect value was specified for the attribute, correct the program and try the service again.

Symbolic Identifier (value)
EIMERR_ATTR_NOTSUPP (6)
ITY0008     CCSID is outside of valid range or CCSID is not supported.

Explanation
Not returned on EIM for z/OS.

System action
None.

Programmer response
None.

Symbolic Identifier (value)
EIMERR_CONFIG_SIZE (10)
ITY0011    Connection already exists.

Explanation
An attempt was made to use an EIM handle that already has a connection established with an EIM domain.

System action
The invoked function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_CONN (11)
ITY0012    Connection type is not supported.
Explanation
The value specified for the connection type is either not a valid connection type or not supported on this platform.

System action
The called function fails.

Programmer response
Check the documentation for the EIM API and verify the connection type is supported. If the connection type is not supported or an incorrect value was specified for the attribute, correct the program and try the service again.

Symbolic Identifier (value)
EIMERR_CONN_NOTSUPP (12)

ITY0013 Error occurred when converting data between code pages.

Explanation
Not returned on EIM for z/OS.

System action
None.

Programmer response
None.

Symbolic Identifier (value)
EIMERR_DATA_CONVERSION (13)

ITY0014 EIM domain entry already exists in EIM.

Explanation
The EIM domain distinguished name specified in the ldapURL parameter is defined on the LDAP host.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_DOMAIN_EXISTS (14)

ITY0015 Cannot delete a domain when it has registries or identifiers.

Explanation
The specified EIM domain could not be deleted because it contains identifiers, registry users, or associations.

System action
The called function fails.

Programmer response
Delete the identifiers, registry users, or associations and try the service again.

Symbolic Identifier (value)
EIMERR_DOMAIN_NOTEMPTY (15)

ITY0016 Length of EimList is not valid. EimList must be at least 20 bytes in length.

Explanation
The value specified for the length of the EimList structure parameter is fewer than 20 bytes.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_EIMLIST_SIZE (16)

ITY0017 EimHandle is not valid.

Explanation
The EIM handle does not contain the expected data and cannot be used with any EIM service.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_HANDLE_INVAL (17)
NameInUseAction is not valid.

Explanation
The value specified for the name in use parameter is not valid.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_IDACTION_INVAL (18)

EIM identifier already exists by this name.

Explanation
The identifier could not be added because another identifier exists in the domain with the same unique name.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_IDENTIFIER_EXISTS (19)

More than one EIM identifier was found that matches the requested identifier name.

Explanation
The eimListIdentifier or eimRemoveIdentifier service found more than one entry that matches the specified identifier name. This can occur when the non-unique name is used for the name parameter.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_PROTECT_INVAL (22)

The protect parameter in EimSimpleConnectInfo is not valid.

Explanation
The value specified for the password protection type is either not a valid protection type or not supported on this platform.

System action
The called function fails.

Programmer response
Check the documentation for the EIM API and verify the password protection type is supported. If the password protection type is not supported or an incorrect value was specified, correct the program and try the service again.

Symbolic Identifier (value)
EIMERR_IDENTIFIER_EXISTS (19)

A restricted character was used in the object name.

Explanation
The EIM API detected one of the following characters in the name:

, = + > < # ; * 

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_CHAR_INVAL (21)

Unexpected LDAP error. %1$s

Explanation
An unexpected LDAP error occurred. The eimrc parameter contains the name of the LDAP service that returned an error and additional diagnostic information.
from the LDAP client and from the LDAP server, if available. The substitution text is:

<table>
<thead>
<tr>
<th>Symbolic Identifier (value)</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EIMERR_LDAP_ERR (23)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ITY0024</td>
<td>EIM domain not found or insufficient access to EIM data.</td>
<td></td>
</tr>
</tbody>
</table>

**System action**
The called function fails.

**Programmer response**
Check the LDAP client publication for information on the failing LDAP service and the returned error values. Also check the EIM API documentation for information on the service being performed. Correct the problem and try the service again.

<table>
<thead>
<tr>
<th>Symbolic Identifier (value)</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EIMERR_NODOMAIN (24)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ITY0025</td>
<td>EIM identifier not found or insufficient access to EIM data.</td>
<td></td>
</tr>
</tbody>
</table>

**Explanation**
The EIM identifier does not exist or the bind distinguished name used to establish a connection with the EIM domain does not have authority to access the EIM data.

**System action**
The called function fails.

**Programmer response**
Verify the bind distinguished name is a member of an EIM access control group that the EIM API requires. Verify the identifier exists in the LDAP directory service. Correct the problem and try the service again.

<table>
<thead>
<tr>
<th>Symbolic Identifier (value)</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EIMERR_NOIDENTIFIER (25)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ITY0026</td>
<td>Unable to allocate internal system object.</td>
<td></td>
</tr>
</tbody>
</table>

**System action**
The called function fails.

**Programmer response**
Verify the bind distinguished name is a member of an EIM access control group that the EIM API requires. Verify the domain exists in the LDAP directory service. Correct the problem and try the service again.

<table>
<thead>
<tr>
<th>Symbolic Identifier (value)</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EIMERR_NOLOCK (26)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ITY0027</td>
<td>No memory available. Unable to allocate required space.</td>
<td></td>
</tr>
</tbody>
</table>

**System action**
The EIM API was unable to memory allocate (malloc) storage.

**Programmer response**
Isolate the reason why the program ran out of storage, correct the problem and try the service again.

<table>
<thead>
<tr>
<th>Symbolic Identifier (value)</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EIMERR_NOMEM (27)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ITY0028</td>
<td>EIM registry not found or insufficient access to EIM data.</td>
<td></td>
</tr>
</tbody>
</table>

**Explanation**
The EIM API could not find the specified registry in the domain or the bind distinguished name did not have access to the registry.
System action
The called function fails.

Programmer response
Verify the correct registry name and domain is specified. Verify the bind distinguished name is a member of an access control group that the EIM API requires. Correct the problem and try the service again.

Symbolic Identifier (value)
EIMERR_NOREG (28)
ITY0029 Registry user not found or insufficient access to EIM data.

Explanation
The EIM API could not find the specified registry user in the domain or the bind distinguished name did not have access to the registry.

System action
The called function fails.

Programmer response
Verify the correct registry user, registry name and domain is specified. Verify the bind distinguished name is a member of an access control group that an EIM API requires. Correct the problem and try the service again.

Symbolic Identifier (value)
EIMERR_NOREGUSER (29)
ITY0030 EIM environment is not configured.

Explanation
The EIM API could not find the specified registry user, registry name and domain is specified. Verify the bind distinguished name is a member of an access control group that an EIM API requires. Correct the problem and try the service again.

Symbolic Identifier (value)
EIMERR_NOTCONFIG (30)
ITY0031 Not connected to LDAP.

Explanation
The EIM API requires an EIM handle that is connected to an EIM domain.

System action
The called function fails.

Programmer response
Issue an eimConnect or eimConnect service for the EIM handle and try the service again.

Symbolic Identifier (value)
EIMERR_NOT_CONN (31)
ITY0032 The system is not configured to connect to a secure port. Connection type of EIM_CLIENT_AUTHENTICATION is not valid.

Explanation
The URL for the EIM domain controller does not begin with ldaps.

System action
The called function fails.

Programmer response
Verify the URL is correct and that the correct option is specified on the EIM API, then try the service again.

Symbolic Identifier (value)
EIMERR_NOT_SECURE(32)
ITY0033  System registry not found.

Explanation
The eimAddApplicationRegistry API requires the name of a system registry. The registry does not exist in the EIM domain or the bind distinguished name (DN) is not a member of one of the access control groups that the eimAddApplicationRegistry API requires.

System action
The called function fails.

Programmer response
Verify the correct system registry name is provided. Verify the bind distinguished name is a member of one of the access control groups that the eimAddApplication registry requires. Correct the problem and try the service again.

Symbolic Identifier (value)
EIMERR_NO_SYSREG (33)

ITY0034  Missing required parameter.

Explanation
A required parameter for the EIM API is missing.

System action
The called function fails.

Programmer response
Check the EIM API documentation, identify the missing parameter, correct the problem, and try the service again.

Symbolic Identifier (value)
EIMERR_PARM_REQ (34)

ITY0035  Pointer parameter is not valid.

Explanation
Not returned by EIM on z/OS

System action
None.

Programmer response
None.

Symbolic Identifier (value)
EIMERR_PTR_INVAL (35)

ITY0036  LDAP connection is for read only.

Explanation
The EIM API tried to add, delete, or change information in an EIM domain, but the EIM handle is connected to an LDAP server that is read only.

System action
The invoked function fails

Programmer response
Create a new handle that is connected to a master LDAP server and try the service again.

Symbolic Identifier (value)
EIMERR_READ_ONLY (36)

ITY0037  Registry entry already exists in EIM.

Explanation
The EIM API tried to add a system or application registry to an EIM domain and a registry with the same name is defined in the domain.

System action
The called function fails.

Programmer response
Create a new handle that is connected to a master LDAP server and try the service again.

Symbolic Identifier (value)
EIMERR_REGISTRY_EXISTS (37)

ITY0038  Requested registry kind is not valid.

Explanation
The value specified for the registry kind is not a valid registry kind.

System action
The called function fails.

Programmer response
None.
Programmer response
Check the documentation for the EIM API, correct the problem, and try the service again.

**Symbolic Identifier (value)**
EIMERR_REGKIND_INVAL (38)

**ITY0039**
Local registry name is too large.

**Explanation**
This is not returned by EIM on z/OS.

**System action**
None.

**Programmer response**
None.

**Symbolic Identifier (value)**
EIMERR_REGNAME_SIZE (39)

**ITY0040**
Cannot delete a registry when an application registry has this system registry defined.

**Explanation**
The specified EIM registry could not be deleted because an application registry is defined for this system registry.

**System action**
The called function fails.

**Programmer response**
Delete the application registry and try the service again.

**Symbolic Identifier (value)**
EIMERR_REG_SPACE (41)

**ITY0042**
EimSSLInfo is required.

**Explanation**
The EIM domain controller URL begins with ldaps, but the SSL information was not specified as a parameter to the EIM API.

**System action**
The called function fails.

**Programmer response**
Correct the EIM domain controller URL or parameter list for the EIM API and try the service again.

**Symbolic Identifier (value)**
EIMERR_REG_NAME (42)

**ITY0043**
Length of unique name is not valid.

**Explanation**
The length of the uniqueName is not 20 bytes longer than the length of the identifier.

**System action**
The called function fails.

**Programmer response**
Correct the error and try the service again.

**Symbolic Identifier (value)**
EIMERR_REG_NOTEMPTY (43)

**ITY0044**
Unknown exception or unknown system state.

**Explanation**
Not returned by EIM on z/OS

**System action**
None.

**Programmer response**
None.
Symbolic Identifier (value)  
EIMERR_UNKNOW (44)  

ITY0045  URL has no distinguished name (required).

Explanation  
The value specified for the *ldapURL* parameter does not contain a distinguished name.

System action  
The called function fails.

Programmer response  
Correct the error and try the service again.

Symbolic Identifier (value)  
EIMERR_URL_NODN (45)  

ITY0046  URL has no domain (required).

Explanation  
The distinguished name portion of the *ldapURL* parameter does not begin with *ibm-eimDomainName=* or *ibm-eimdomainname=*.

System action  
The called function fails.

Programmer response  
Correct the error and try the service again.

Symbolic Identifier (value)  
EIMERR_URL_NODOMAIN (46)  

ITY0047  URL does not have a host.

Explanation  
The value specified for the *ldapURL* parameter does not contain an LDAP host name.

System action  
The called function fails.

Programmer response  
Correct the error and try the service again.

Symbolic Identifier (value)  
EIMERR_URL_NOHOST (47)  

ITY0048  URL has no port (required).

Explanation  
Not returned by EIM on z/OS.

System action  
None.

Programmer response  
None.

Symbolic Identifier (value)  
EIMERR_URL_NOPORT (48)  

ITY0049  URL does not begin with ldap:// or ldaps://.

Explanation  
The value specified for the *ldapURL* parameter does not begin with *ldap://* or *ldaps://*.

System action  
The called function fails.

Programmer response  
Correct the error and try the service again.

Symbolic Identifier (value)  
EIMERR_URL_NOTLDAP (49)  

ITY0050  LDAP connection can only be made to a replica LDAP server.

Explanation  
The EIM API requires a connection to a master or writable server.

System action  
The called function fails.

Programmer response  
Correct the error and try the service again.

Symbolic Identifier (value)  
EIMERR_URL_READ_ONLY (50)  

ITY0051  Configuration URL is too large.
Explanation
Not returned by EIM on z/OS

System action
None.

Programmer response
None.

Symbolic Identifier (value)
EIMERR_URL_SIZE (51)

ITY0052  The EimIdType value is not valid.

Explanation
The value specified for the type of identifier is not one of the allowed values.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_IDNAME_TYPE_INVAL (52)

ITY0053  Length of EimAttribute is not valid.

Explanation
The length of the value for the handle attribute is fewer than 8 bytes.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_ATTRIB_SIZE (53)

ITY0054  Connection type is not valid.

Explanation
The value specified for the connection type is either not a correct connection time or not supported on this platform.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_CONN_INVAL (54)

ITY0055  Registry name must be NULL when access type is not EIM_ACCESS_REGISTRY.

Explanation
The value specified for the access type requires the registry name parameter to be NULL.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_REG_MUST_BE_NULL (55)

ITY0056  Unexpected object violation.

Explanation
The EIM API attempted to retrieve the entry UUID attribute for an LDAP entry and it was not returned.

System action
The called function fails.

Programmer response
Contact your LDAP administrator or system programmer. Provide this person with the name of the EIM API and the error number (errno) and error string.

Symbolic Identifier (value)
EIMERR_UNEXP_OBJ_VIOLATION (56)

ITY0057  Reserved field is not valid.

Explanation
Not returned by EIM on z/OS
System action
None.

Programmer response
None.

Symbolic Identifier (value)
EIMERR_RESERVE_INVAL (57)

ITY0058 Credentials must be NULL for the specified connection type.

Explanation
The connection info parameter of the EIM API does not have a NULL value for the creds field in the connection info structure.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_CREDS_MUST_BE_NULL (58)

ITY0059 Error occurred after the domain object was created.

Explanation
The EIM API was unable to create the groups, identifier, source mappings, or registries containers in the EIM domain. The domain is in an unusable state. The return code is the value returned from an ldap_add_s service.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_NOPOLICYFILTER (60)

ITY0060 Policy filter type is not valid.

Explanation
The value specified for the policy filter type parameter is not a valid policy filter type.

System action
The called function fails.

Programmer response
Refer to the API documentation for valid policy filter types, correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_POLICY_FILTER_TYPE_INVAL (60)

ITY0061 Policy filter value not found for the specified registry.

Explanation
The filter value is not defined for the source registry.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_REGTYPE_INVAL (62)

ITY0062 Registry type is not valid.

Explanation
The value specified for the registry type is not one of the supported values.

System action
The called function fails.

Programmer response
Refer to the API documentation for valid registry types, correct the error, and try the service again.

Symbolic Identifier (value)
EIMERR_REGTYPE_INVAL (62)

ITY0063 User identity type is not valid.
Explanation
The value specified for the user identity type parameter is not a valid type.

System action
The called function fails.

Programmer response
Refer to the API documentation for valid user identity types, correct the error, and try the service again.

Symbolic Identifier (value)
EIMERR_USER.IDENTITY.TYPE_INVAL (63)

ITY0064 Length of EimUserIdentity is not valid.

Explanation
The value specified for the length of the user identity information structure parameter is not sufficient. The minimum storage required for the user identity information structure is 16 bytes.

System action
The called function fails.

Programmer response
Obtain a larger block of storage for the user identity information structure and update the length value with the new size. Then try the eimFormatUserIdentity service again.

Symbolic Identifier (value)
EIMERR_USER.IDENTITY.SIZE (64)

ITY0065 User identity format type is not valid.

Explanation
The value specified for the format type parameter is not a valid type.

System action
The called function fails.

Programmer response
Change the user identity format type parameter to a supported value, and try the service again.

Symbolic Identifier (value)
EIMERR_USER.IDENTITY_FORMAT.TYPE_INVAL (65)

ITY0066 Distinguished Name (DN) is not valid.

Explanation
An error occurred while attempting to parse a distinguished name. The DN may have been specified as a parameter or extracted from a certificate parameter.

System action
The called function fails.

Programmer response
Correct the parameter in error and try the service again.

Symbolic Identifier (value)
EIMERR_INVALID_DN (66)

ITY0067 Certificate data is not valid.

Explanation
An error occurred while decoding or parsing the certificate parameter.

System action
The called function fails.

Programmer response
Programmer Response: Ensure the certificate parameter is a valid base64 or DER encoded X.509 certificate.

Symbolic Identifier (value)
EIMERR_CERTIFICATE_INVAL(67)

ITY0068 Configuration format is not valid.

Explanation
The value specified in the configuration info parameter for the configuration format is not a valid type.

System action
The called function fails.

Programmer response
Correct the error and try the service again.
Symbolic Identifier (value)
EIMERR_CONFIG_FORMAT_INVAL (68)

**ITY0069** The specified type is not valid.

**Explanation**
The value specified for the type parameter is not a valid.

**System action**
The called function fails.

**Programmer response**
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_TYPE_INVAL (69)

**ITY0070** The specified function is not supported by the EIM version.

**Explanation**
The application called a function that requires that the EIM domain controller (the LDAP Server) have new schema elements that were not found on the connected domain controller.

**System action**
The called function fails.

**Programmer response**
Use an EIM domain controller that has the requisite support, or upgrade the existing EIM domain controller to the minimum requisite level.

Symbolic Identifier (value)
EIMERR_FUNCTION_NOT_SUPPORTED (70)

**ITY0071** Unable to find LDAP schema.

**Explanation**
An attempt to obtain the subschemasubentry suffix failed for the specified, configured, or connected EIM domain controller.

**System action**
The called function fails.

Symbolic Identifier (value)
EIMERR_LDAP_SCHEMA_NOT_FOUND (71)

**ITY3300E** Authentication Context exception.
Length not correct for "{0}". Length found: {1}. Available length: {2}.

**Explanation**
A length inconsistency was detected in an internal identity context data structure.

**System action**
Processing stops.

**User response**
Ensure the specified identity context is valid. If the problem recurs, contact the IBM support center.

Symbolic Identifier (value)
EIMERR_FUNCTION_NOT_SUPPORTED (70)

**ITY3301E** Authentication Context exception.
The specified array is not large enough to contain identity context headers.

**Explanation**
An error was detected while parsing an identity context. The length of the specified array is not large enough to hold a valid identity context.

**System action**
Processing stops.

**User response**
Ensure the specified identity context is valid. If the problem recurs, contact the IBM support center.

Symbolic Identifier (value)
EIMERR_FUNCTION_NOT_SUPPORTED (70)

**ITY3302E** Authentication Context exception.
The value of the "length" field {0} does not match the length of the array {1}.

**Explanation**
A length inconsistency was detected in an internal identity context data structure.

**System action**
Processing stops.
Ensure the specified identity context is valid. If the problem recurs, contact the IBM support center.

**ITY3303E**  
**Authentication Context exception.**  
OID not correct for Type 1 authentication context.

**Explanation**  
The OID from the specified identity context does not match the Type 1 authentication context OID. The method called can only process identity contexts which are Type 1 authentication contexts.

**System action**  
Processing stops.

**User response**  
Ensure identity context is a Type 1 authentication context and retry the method.

**ITY3304E**  
**Authentication Context exception.**  
OID in authentication context does not match Type 1 OID.

**Explanation**  
The internal OID from the specified identity context does not match the Type 1 authentication context OID. The method called can only process identity contexts which are Type 1 authentication contexts.

**System action**  
Processing stops.

**User response**  
Ensure identity context is a Type 1 authentication context and retry the API.

**ITY3350E**  
**Identity Context exception.**  
Identity Context not found.

**Explanation**  
An identity context could not be retrieved for the specified context credentials. The context credentials may not have been valid or may have timed out.

**System action**  
Processing stops.

**User response**  
Ensure the context credentials are valid and are used before they time out.

**ITY3351E**  
**Identity Context exception.**  
Identity Context damaged.

**Explanation**  
Not returned on z/OS.

**System action**  
None.

**User response**  
None.

**ITY3352E**  
**Identity Context exception.**  
Error in API: `{0}`. Exception from EIM. EIM Exception: `{1}`.

**Explanation**  
Not returned on z/OS.

**System action**  
None.

**User response**  
None.

**ITY3353E**  
**Missing required parameter.**  
"{0}"

**Explanation**  
A required parameter was not supplied.

**System action**  
Processing stops.

**User response**  
Supply the required parameter and retry the API.

**ITY3354E**  
**Illegal argument for parameter:**  
"{0}"

**Explanation**  
A parameter contains an illegal or inappropriate argument.

**System action**  
Processing stops.

**User response**  
Consult the Javadoc for the correct parameter syntax. Correct the illegal parameter value and retry the method.
ITY3355E  Input class not expected class type. Expected class: "{0}"

**Explanation**
A parameter is not of the expected class type. The returned exception will include a substitution for the expected class.

**System action**
Processing stops.

**User response**
Ensure all parameters match the method signature. Use expected class to resolve the problem and try the method again.

ITY4001  Error *errno* returned from attempt to open message catalog file -- *errnoText*

**Explanation**
The utility failed to open the message catalog named *file*. The open attempt sets the error code *Errno*. *errnoText* is the associated explanation.

**System action**
The utility fails.

**User response**
Possible causes for this message include an incomplete NLSPATH definition or insufficient access to the file. Correct the problem and restart the utility.

ITY4002  Error *errno* returned from attempt to retrieve message from catalog file -- *errnoText*

**Explanation**
The utility failed to read a message from the message catalog named *file*. The read attempt sets the error code *Errno*. *errnoText* is the associated explanation.

**System action**
The utility fails.

**User response**
Possible causes for this message include a corrupt catalog file or a file having a different service level than the utility. Correct the problem and restart the utility.

ITY4010  No argument value specified for option *character*.

**Explanation**
The option *character* specified requires an argument value, but none was specified.

**System action**
The utility fails.

**User response**
Restart the utility specifying a value for the indicated option, or omit the option altogether.

ITY4011  Option *character* not recognized. Specify '-?' for utility syntax.

**Explanation**
The *character* specified is not a defined option.

**System action**
The utility fails.

**User response**
You can review utility syntax by specifying the -? option. Restart the utility specifying correct option characters.

ITY4012  *option* not specified.

**Explanation**
The *option* names the entity that is required for the function but was not specified through a command line option or input data record.

**System action**
The utility fails.

**User response**
Restart the utility, making sure to include a value for the requested option.

ITY4013  Specified type value not supported -- *value*

**Explanation**
*Type* describes the entity for which an unsupported *value* was specified.

**System action**
The utility fails.

**User response**

User response
Refer to the utility documentation for allowable entity values. Restart the utility, specifying an allowable value.

ITY4014  Specified combination of action 'character' and object type 'character' not supported.

Explanation
The utility does not offer any function corresponding to the specified action and object option combination as indicated by character.

System action
The utility fails.

User response
Choose another option combination and restart the utility.

ITY4015  Please enter LDAP bind password for bindDN:

Explanation
The utility prompts for an LDAP bind password if not specified as a command line option. The password should be the one associated with the LDAP bindDN specified.

System action
The utility allows the user one chance to input a non-NULL password value. If one is not specified, the utility fails.

User response
Enter the password as requested. The value will not be displayed.

ITY4016  Please enter key file password for fileName:

Explanation
The utility prompts for an SSL key database file password if the specified file exists but its password was not specified as a command line option. The password should be the one associated with the fileName specified. Alternatively, you can specify an SSL password stash file by prefixing the stash file name with "file://".

System action
The utility allows the user one chance to input a non-NULL password value. If one is not specified, the utility fails.

User response
Enter the password as requested. The value will not be displayed.

ITY4017  Domain DN must be a distinguished name beginning with 'ibm-eimDomainName='.

Explanation
The value specified is incorrect or incomplete.

System action
The utility fails.

User response
Restart the utility, making sure the domain value is a distinguished name beginning with 'ibm-eimDomainName='.

ITY4020  eimadmin (version) started time with options commandLine

Explanation
The utility issues this informational message when beginning its processing of input records. Version indicates the program level. Time indicates the date and time that processing began. CommandLine is an approximation of the string issued to start the utility.

System action
Processing continues.

User response
User Response:
None.

ITY4021  Processing ended normally.

Explanation
The utility processed all records from the input file; however, errors might have occurred along the way.

System action
The utility stops.
User response
Check the preceding ITY4022 message to learn if any errors occurred. If so, correct them and, if appropriate, restart the utility against a file of the previously-failing records.

ITY4022  Count records processed -- successCount successful; failCount failed.

Explanation
When processing an input file, the utility issues this message as a progress indicator one time every 50 records and as a completion summary statement. Count is the number of data lines processed from the input file. SuccessCount is the number processed without error, while failCount indicates the number of records for which errors occurred. The count value at the end of processing should equal the number of data lines in the input file if message ITY4021 is issued.

System action
The utility continues if there are remaining unprocessed input records unless a severe error has occurred.

User response
If failCount is greater than zero, errors occurred. Review preceding error messages to determine where and why errors occurred. Correct the errors and, if appropriate, restart the utility against a file of the previously-failing records.

ITY4023  Processing stopped due to error.

Explanation
The utility stopped processing before reaching the end of data records in the input file because it encountered a severe error.

System action
The utility stops.

User response
The last data record error message should identify the problem, but less severe errors might have occurred as well. Review the error messages to determine where and why errors occurred. Correct the errors and, if appropriate, restart the utility against a file of the previously-failing records.

ITY4024  Label definition line not found in input file.

Explanation
The utility reached the end of the input file without identifying the label definition line.

System action
The utility stops.

User response
Verify the input file specified is the one intended and that it has a label line that is not prefixed with a comment character. Restart the utility, specifying an input file with proper syntax.

ITY4025  Unrecognized label found starting at column position on input line number.

Explanation
The utility detected characters in the first non-blank, non-comment line that do not constitute a supported label. Position is the character offset from the beginning of the line, identified by number.

System action
The utility stops.

User response
Verify the input file specified is the one intended and that the label line contains only supported labels. Restart the utility, specifying an input file with proper syntax.

ITY4026  Missing final label delimiter 'character' on input line number.

Explanation
The utility did not find the required field delimiter, character, at the end of the label line, which is line number of the input file.

System action
The utility stops.

User response
Insert the missing delimiter and restart the utility.

ITY4027  Length of input line number exceeds limit characters.

Explanation
The length of input file line number is greater than the allowed limit.

<tr>
<td>ITY4042 Specified combination of option option1 and option2 is not supported.</td>
<td></td>
</tr>
</tbody>
</table>
Explanation
The utility failed during validation of the specified options. The options option1 and option2 may not be specified in conjunction with each other.

System action
The utility stops if a severe error occurred; otherwise it continues processing data records.

Programmer response
Correct the problem by removing one of the options and try the command again.

ITY4043  Could not find the certificate file -- service -- error text

Explanation
The utility performed validation of the certificate file specified which failed. The indicated service did not succeed and the problem encountered is described in the included error text. The specified certificate file may not exist, may be a zero length file, or may not be a regular file or symbolic link to a regular file.

System action
The utility stops if a severe error occurred; otherwise it continues processing data records.

Programmer response
The error text in the message should indicate the problem. If not, refer to error documentation for the service. Correct the error and restart the utility.

ITY4046  Expected string "-----END CERTIFICATE-----" not found

Explanation
The certificate file name passed to the utility encountered a base64 decoding problem. The "-----BEGIN CERTIFICATE-----" text string was found but the corresponding "-----END CERTIFICATE-----" text string was not found in the certificate file.

System action
The utility stops if a severe error occurred; otherwise it continues processing data records.

Programmer response
Specify a valid certificate file and run the utility command again.

ITY6002  RACROUTE REQUEST=EXTRACT error retrieving EIM configuration information from the caller's USER profile. %1$s

Explanation
The EIM API failed while retrieving EIM information from RACF. A RACROUTE REQUEST=EXTRACT error occurred while retrieving the EIM segment from the caller's USER profile. Failing user ID and return codes appear in the EimRC substitution text. The substition text is:

USER(user id ) SAF RC(xxxxxxxx) RACF RC(xxxxxxxx) RACF RSN(xxxxxxxx)

The return and reason codes are in hex. The RACROUTE return codes are documented in z/OS Security Server RACROUTE Macro Reference.

System action
The called function fails.

Programmer response
Use the return codes to resolve the problem in the user EIM segment and try the service again.
Symbolic Identifier (value)
EIMERR_ZOS_USER_XTR (6002)

ITY6003 RACROUTE REQUEST=EXTRACT error retrieving EIM information from a RACF profile. %1$s

Explanation
The EIM API failed while retrieving EIM information from RACF. A RACROUTE REQUEST=EXTRACT error occurred while retrieving the EIM segment from a RACF profile. Failing user ID, class, profile name and return codes appear in the EimRC substitution text. The substitution text is:

| USER(user ID) | CLASS(class) | PROFILE(profile name) | SAF RC(xxxxxxxx) | RACF RC(xxxxxxxx) | RACF RSN(xxxxxxxx) |

The return and reason codes are in hex. The RACROUTE return codes are documented in z/OS Security Server RACROUTE Macro Reference.

System action
The called function fails.

Programmer response
Use the return codes to resolve the problem in the profile and try the service again.

Symbolic Identifier (value)
EIMERR_ZOS_XTR_DOMAINDN (6004)

ITY6005 RACROUTE REQUEST=EXTRACT error retrieving PROXY information from a RACF profile. %1$s

Explanation
The EIM API failed while retrieving PROXY information from RACF. A RACROUTE REQUEST=EXTRACT error occurred while retrieving the PROXY segment from a RACF profile. Failing user ID, class, profile name and return codes will appear in the EimRC substitution text. The substitution text is:

| USER(user id) | CLASS(class) | PROFILE(profile name) | SAF RC(xxxxxxxx) | RACF RC(xxxxxxxx) | RACF RSN(xxxxxxxx) |

The return and reason codes are in hex. The RACROUTE return codes are documented in z/OS Security Server RACROUTE Macro Reference.

System action
The called function fails.

Programmer response
Use the return codes to resolve the problem in the profile and try the service again.

Symbolic Identifier (value)
EIMERR_ZOS_XTR_EIM (6003)

ITY6004 EIM domain distinguished name is missing. %1$s

Explanation
The EIM API failed while retrieving EIM information from RACF. The EIM segment DOMAINDN field has a length of zero. Failing user ID, class and profile name appear in the EimRC substitution text. The substitution text is:

| USER(user id) | CLASS(class) | PROFILE(profile name) |

System action
The called function fails.

Programmer response
Ensure the EIM segment DOMAINDN field is defined properly and try the service again.

Symbolic Identifier (value)
EIMERR_ZOS_XTR_PROXY (6005)

ITY6006 PROXY LDAP host is missing. %1$s

Explanation
The EIM API failed while retrieving PROXY information from RACF. The PROXY segment LDAPHOST field has a length of zero. Failing user ID, class and profile name appear in the EimRC substitution text. The substitution text is:

| USER(user id) | CLASS(class) | PROFILE(profile name) |

System action
The called function fails.

Programmer response
Ensure the PROXY segment LDAPHOST field is defined properly and try the service again.

Messages 97
Symbolic Identifier (value)
EIMERR_ZOS_XTR_LDAPHOST (6006)

**ITY6007** PROXY bind distinguished name is missing. %1$s

**Explanation**
The EIM API failed while retrieving PROXY information from RACF. The PROXY segment BINDDN field has a length of zero. Failing user ID, class and profile name appear in the EimRC substitution text. The substitution text is:

```
USER(user id) CLASS(class) PROFILE(profile name)
```

**System action**
The called function fails.

**Programmer response**
Ensure the PROXY segment BINDDN field is defined properly and try the service again.

Symbolic Identifier (value)
EIMERR_ZOS_XTR_BINDDN (6007)

**ITY6008** R_DCEKEY callable service failed. %1$s

**Explanation**
The EIM API failed while retrieving PROXY information from RACF. An error occurred during R_DCEKEY callable service processing. The PROXY segment BINDPW field has a length of zero. Failing user ID, class, profile name and return codes appear in the EimRC substitution text. The substitution text is:

```
USER(user id) CLASS(class) PROFILE(profile name)
SAF RC(xxxxxxxx) RACF RC(xxxxxxxx) RACF RSN(xxxxxxxx)
```

The return and reason codes are in hex. The R_DCEKEY return codes are documented in z/OS Security Server RACF Callable Services.

**System action**
The called function fails.

**Programmer response**
Ensure the PROXY segment BINDPW field is defined properly and try the service again.

Symbolic Identifier (value)
EIMERR_ZOS_R_DCEKEY_BINDPW (6009)

**ITY6010** No task or address space ACEE was found.

**Explanation**
The EIM API service failed because a task or address space ACEE could not be found.

**System action**
The called function fails.

**Programmer response**
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_ZOS_NO_ACEE (6010)

**ITY6011** Error occurred when converting data between code pages. %1$s

**Explanation**
An error occurred when converting data between code pages. Check the EimRC substitution text for more specific code page errors. The EIM API is unable to determine the current code page or cannot translate
between the code pages specified in the substitution text. The substitution text is:

```
Failed converting to UTF-8 from <current locale codeset>
```

**System action**
The called function fails.

**Programmer response**
Correct the error and try the service again.

**Symbolic Identifier (value)**
EIMERR_ZOS_DATA_CONVERSION (6011)

**ITY6012** The EIM API is not supported.

**Explanation**
The called function is not available to z/OS programs.

**System action**
The called function fails.

**Programmer response**
Check the documentation for the EIM API for alternative methods of providing the function. Correct the program and try the service again.

**Symbolic Identifier (value)**
EIMERR_USERID_MUST_BE_NULL(6015)

**ITY6016** The length of the specified profile name is not valid.

**Explanation**
The EIM API failed verification of the value specified for the profile name. The profile name passed exceeded the maximum length for a profile which is 246 characters.

**System action**
The called function fails.

**Programmer response**
Correct the error and try the service again.
Symbolic Identifier (value)
EIMERR_PROFILE_SIZE (6016)

**ITY6017**  The length of the specified user identity is not valid.

**Explanation**
The EIM API failed verification of the value specified for the user identity. The value passed for the user identity exceeded the maximum length which is 8 characters.

**System action**
The called function fails.

**Programmer response**
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_USERID_SIZE (6017)

**ITY6018**  The bind password is missing in the specified profile. %1$s

**Explanation**
The EIM API failed while retrieving the BINDPW field of the PROXY segment from the specified profile. The PROXY segment BINDPW field has a length of zero. Failing user ID, class and profile name appear in the EimRC substitution text. The substitution text is:

```
USER(user id) CLASS(class) PROFILE(profile name)
```

**System action**
The called function fails.

**Programmer response**
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_ZOS_BINDPW_SIZE (6019)

**ITY6020**  The length of the specified bind distinguished name is not valid.

**Explanation**
The EIM API failed verification of the value specified for the bind distinguished name (DN). The value passed exceeds the maximum length allowed which is 1023 characters.

**System action**
The called function fails.

**Programmer response**
Ensure the PROXY segment BINDDN field is defined properly and try the service again.

Symbolic Identifier (value)
EIMERR_ZOS_BINDDN_SIZE (6020)

**ITY6021**  The RACF command invoked by the R_admin callable service failed - %1$s

**Explanation**
The EIM API failed while attempting to create, update, or delete a security product profile with the R_admin callable service. If the calling program passed an EimRC structure pointer to the API, the substitution text will contain the return and reason codes returned from R_admin, the failing command string passed to R_admin, and any error messages returned from the R_admin callable service. The substitution text is:

```
R_admin command(command string)
SAF RC(return code) RACF RC(return code)
RACF RSN(reason code)
Command error message 1
Command error message 2
...
```

The return and reason codes are in decimal. The R_admin callable service return and reason codes are documented in z/OS Security Server RACF Callable Services.
System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_ZOS_RADMIN_CMD_ERROR (6021)

Error message 1

Explanation
The EIM API failed while attempting to call the R_admin callable service. If the calling program passed an EimRC structure pointer to the API, the substitution text will contain the return and reason codes returned from R_admin, the command string passed to R_admin, and any error messages returned from the R_admin callable service. The substitution text is:

R_admin command(command string)
SAF RC(return code) RACF RC(return code)
RACF RSN(reason code)
Command error message 1
Command error message 2
...

The return and reason codes are in decimal. The R_admin callable service return and reason codes are documented in z/OS Security Server RACF Callable Services.

System action
The called function fails.

Programmer response
Correct the error and try the service again.

Symbolic Identifier (value)
EIMERR_ZOS_RGETINFO_AUTH (6023)

Error message 2

Explanation
The EIM API failed while retrieving EIM information from RACF. The R_GetInfo callable service returned a field-level access check failure. Failing user ID, class, profile name and return codes 365 appear in the EimRC substitution text. The substitution text is:

USER(user ID) CLASS(class) PROFILE(profile name)
SAF RC(xxxxxxxx) RACF RC(xxxxxxxx) RACF
RSN(xxxxxxxx)

The EimRC substitution text can contain null values, such as USER(), for parameters which are not applicable to the failing request. The return and reason codes are in hex. The R_GetInfo return codes are documented in z/OS Security Server RACF Callable Services.

System action
The called function fails.

Programmer response
Use the return codes to resolve the R_GetInfo problem and try the service again.

Symbolic Identifier (value)
EIMERR_ZOS_RGETINFO_FLAC (6024)
ITY6025 The R_GetInfo callable service failed. Extract failed. %1$s

Explanation
The EIM API failed while retrieving EIM information from RACF. The R_GetInfo callable service encountered an unexpected error while attempting to extract EIM information. Failing user ID, class, profile name and return codes appear in the EimRC substitution text. The substitution text is:

USER(user ID) CLASS(class) PROFILE(profile name)
SAF RC(xxxxxxxxx) RACF RC(xxxxxxxxx) RACF RSN(xxxxxxxxx)

The EimRC substitution text can contain null values, such as USER(), for parameters not applicable to the failing request. The return and reason codes are in hex. The R_GetInfo return codes are documented in z/OS Security Server RACF Callable Services.

System action
The called function fails.

Programmer response
Use the return codes to resolve the R_GetInfo problem and try the service again.

Symbolic Identifier (value)
EIMERR_ZOS_RGETINFO_ERROR (6026)

ITY6027 Error retrieving EIM configuration information from the caller's USER profile. %1$s

Explanation
The EIM API failed while retrieving EIM information from RACF. An R_GetInfo callable service error occurred while retrieving the EIM segment from the caller's USER profile. Failing user ID and return codes appear in the EimRC substitution text. The substitution text is:

USER(user ID) SAF RC(xxxxxxxxx) RACF RC(xxxxxxxxx)
RACF RSN(xxxxxxxxx)

The return and reason codes are in hex. The R_GetInfo return codes are documented in z/OS Security Server RACF Callable Services.

System action
The called function fails.

Programmer response
Use the return codes to resolve the problem in the user EIM segment and try the service again. If the substitution text does not contain values for SAF RC, RACF RC, and RACF RSN, the required profile or segment was not found.

Symbolic Identifier (value)
EIMERR_ZOS_USER_XTR (6027)

ITY6028 Error retrieving EIM information from a RACF profile. %1$s

Explanation
The EIM API failed while retrieving EIM information from RACF. An R_GetInfo callable service error occurred while retrieving the EIM segment from a RACF profile. Failing user ID, class, profile name and return codes appear in the EimRC substitution text. The substitution text is:

USER(user ID) CLASS(class) PROFILE(profile name)
SAF RC(xxxxxxxxx) RACF RC(xxxxxxxxx) RACF RSN(xxxxxxxxx)

The return and reason codes are in hex. The R_GetInfo return codes are documented in z/OS Security Server RACF Callable Services.

System action
The called function fails.
The return and reason codes are in hex. The R_GetInfo return codes are documented in z/OS Security Server RACF Callable Services.

System action
The called function fails.

Programmer response
Use the return codes to resolve the problem in the profile and try the service again. If the substitution text does not contain values for SAF RC, RACF RC, and RACF RSN, the required profile or segment was not found.

Symbolic Identifier (value)
EIMERR_ZOS_XTR_EIM (6028)

ITY6029 Error retrieving PROXY information from a RACF profile. %1$s

Explanation
The EIM API failed while retrieving PROXY information from RACF. An R_GetInfo callable service error occurred while retrieving the PROXY segment from a RACF profile. Failing user ID, class, profile name and return codes appear in the EimRC substitution text. The substitution text is:

USER(user ID) CLASS(class) PROFILE(profile name)
SAF RC(xxxxxxxx) RACF RC(xxxxxxxx) RACF RSN(xxxxxxxx)

The return and reason codes are in hex. The R_GetInfo return codes are documented in z/OS Security Server RACF Callable Services.

System action
The called function fails.

Programmer response
Use the return codes to resolve the problem in the profile and try the service again. If the substitution text does not contain values for SAF RC, RACF RC, and RACF RSN, the required profile or segment was not found.

Symbolic Identifier (value)
EIMERR_ZOS_XTR_PROXY (6029)

ITY6500E com.ibm.ictx.identitycontext.zOS StorageMechanism is only valid on z/OS release 1.8 or later systems.

Explanation
The zOSStorageMechanism was instantiated on an unsupported system.

System action
Processing stops.

User response
Utilize the StorageMechanismFactory and the LdapStorageMechanism for remote access to the identity cache.

ITY6501E Length of "{0}" is not valid. Length found: {1}. Length must be exactly: {2}.

Explanation
A specified parameter has an invalid length.

System action
Processing stops.

User response
Correct the invalid length and retry the method.

ITY6502E The R_cacheserv callable service failed. {0}

Explanation
The method failed while attempting to call the R_cacheserv callable service. The returned exception text will contain the return and reason codes from R_cacheserv. The substitution text is:

SAF RC(return code) RACF RC(return code) RACF RSN(reason code)

System action
Processing stops.

User response
Use the return and reason codes to resolve the R_cacheserv problem and try the method again.

ITY6503E The R_cacheserv callable service failed. Not authorized to use this service. {0}

Explanation
The method failed while attempting to call the R_cacheserv callable service. R_cacheserv return and reason codes indicate an authorization failure. The
returned exception text will contain the return and reason codes from R_cacheserv. The substitution text is:

```plaintext
SAF RC(return code) RACF RC(return code) RACF RSN(reason code)
```

**System action**
Processing stops.

**User response**
Use the return and reason codes to resolve the R_cacheserv problem and try the method again.

**ITY6504E** The R_cacheserv callable service failed. The length of the identity context record is not valid. {0}

**Explanation**
The method failed while attempting to call the R_cacheserv callable service. R_cacheserv return and reason codes indicate that the identity context is too large to store successfully. The returned exception text will contain the return and reason codes from R_cacheserv. The substitution text is:

```plaintext
SAF RC(return code) RACF RC(return code) RACF RSN(reason code)
```

**System action**
Processing stops.

**User response**
Use the return and reason codes to resolve the R_cacheserv problem and try the method again.

**ITY6505E** Error calling EIM API: "{0}". EIM error message: "{1}"

**Explanation**
The method failed while attempting to call an EIM API. Another error occurred while calling eimErr2String to access the EIM message. The returned exception will include substitutions for the failing EIM API name and the eimErr2String errno text.

**System action**
Processing stops.

**User response**
Use the EIM API name and eimErr2String errno text to resolve the EIM problem and try the method again.

**ITY6506E** Configuration prevents store requests: USEMAP(NO) DOMAP(NO) MAPREQUIRED(YES).

**Explanation**
The current ICTX configuration does not allow store requests. MAPREQUIRED(YES) requires a local mapping, but both USEMAP and DOMAP are disabled.

**System action**
Processing stops.

**User response**
If a local mapping is desired, enable USEMAP and/or DOMAP. If a local mapping is not desired, disable MAPREQUIRED.

**ITY6507E** Configuration allows only Type 1 authentication contexts be stored: MAPREQUIRED(YES).

**Explanation**
The current ICTX configuration requires a local mapping but the provided identity context was not a Type 1 authentication context. In order to perform a local mapping, information must be parsed from a Type 1 authentication context.

**System action**
Processing stops.

**User response**
If a local mapping is desired, a Type 1 authentication context must be provided. If an alternate identity context is desired, enable USEMAP and/or DOMAP. If an alternate identity context is not desired, disable MAPREQUIRED.
context is to be stored, MAPREQUIRED must be disabled.

| ITY6509E | Configuration prevents store requests: Local registry must be configured with MAPREQUIRED(YES). |

**Explanation**
The current ICTX configuration indicates local mapping is required but the local registry is not configured. In order to perform a local mapping with USEMAP or DOMAP, the local registry must be configured.

**System action**
Processing stops.

**User response**
If a local mapping is desired, use RACF commands to configure the local registry. If a local mapping is not desired, disable MAPREQUIRED.

| ITY6510E | Store request failed. Configuration requires local mapping: MAPREQUIRED(YES). {0} {1} |

**Explanation**
The current ICTX configuration indicates local mapping is required but both USEMAP and DOMAP could not be successfully completed. The substitution text indicates the reasons why USEMAP and DOMAP could not be completed.

**USEMAP substitutions:**
- Configuration does not allow premapped data: USEMAP(NO).
- Premapped data was not provided.
- The registry from the premapped data did not match the configured local registry.
- The user from the premapped data does did have a valid length. Valid values are 1 to 8.

**DOMAP substitutions:**
- Configuration does not allow local mapping: DOMAP(NO).
- Local mapping was not found.
- Multiple local mappings were found.
- Local mapping found, but length is not valid. Valid values are 1 to 8.
- Could not perform local mapping. Source user was not found.
- Could not perform local mapping. Source registry was not found.

**System action**
Processing stops.

**User response**
If a local mapping is desired, use the exception text to resolve the USEMAP and/or DOMAP problem and try the method again. If a local mapping is not desired, disable MAPREQUIRED.

| ITY6511E | Error processing returned identity context. RecordName size is not valid. |

**Explanation**
A length inconsistency was detected in an internal identity context data structure.

**System action**
Processing stops.

**User response**
If the problem recurs, contact the IBM support center.

| ITY6512E | Error processing returned identity context. RecordName eyecatcher not valid. |

**Explanation**
A invalid data structure identifier (eyecatcher) was detected in an internal identity context data structure.

**System action**
Processing stops.

**User response**
If the problem recurs, contact the IBM support center.

| ITY6513E | Error processing returned identity context. RecordName version not valid. |

**Explanation**
An invalid version was detected in an internal identity context data structure.

**System action**
Processing stops.

System action
Processing stops.

User response
If the problem recurs, contact the IBM support center.

ITY6521E An exception was caught while attempting codepage convert to encoding: {0}. Root exception: {1}

Explanation
An exception was caught while attempting a codepage conversion. The returned exception will include substitutions for the encoding name and root exception text.

System action
Processing stops.

User response
Use the encoding name and root exception text to resolve the problem and try the method again. Ensure the international version of the JRE, which contains the Extended Encoding Set (contained in lib/charsets.jar), has been installed.

ITY6522E Unable to load JNI library: {0}.

Explanation
An error was detected while attempting to load a JNI library. The returned exception will include a substitution for the JNI library name.

System action
Processing stops.

User response
JNI libraries are operating system specific. Ensure that the caller is on a supported OS and release. Ensure that the JNI library is in the caller's PATH and that the caller has at least read access. Retry the method.

ITY6523E Error detected while retrieving configuration information. RCVI pointer is not valid.

Explanation
An error was detected while attempting to load configuration information. An invalid pointer to the RCVI configuration information was detected.

System action
Processing stops.

User response
Attempt to refresh the configuration information by RACLISTERFRESHing the LDAPBIND class and try the method again. If the problem recurs, contact the IBM support center.

ITY6524E Error detected while retrieving configuration information. Active table pointer is not valid.

Explanation
An error was detected while attempting to load configuration information. An invalid pointer in the RCVI was detected.

System action
Processing stops.

User response
Attempt to refresh the configuration information by RACLISTERFRESHing the LDAPBIND class and try the method again. If the problem recurs, contact the IBM support center.

ITY6525E Error detected while retrieving configuration information. Version is not valid.

Explanation
An error was detected while attempting to load configuration information. An invalid version in the RCVI was detected.

System action
Processing stops.

User response
Attempt to refresh the configuration information by RACLISTERFRESHing the LDAPBIND class and try the method again. If the problem recurs, contact the IBM support center.

ITY6526E Error processing R_dcekey results. BINDPW returned with zero length.
Explanation
The method failed while attempting to parse BINDPW configuration information returned from the R_dcekey callable service.

System action
Processing stops.

User response
Use the return and reason codes to resolve the R_dcekey problem and try the method again. Ensure an appropriate ICTX profile is defined and the LDAPBIND class is active and RACLISTed.

ITY6527E  Required LDAP bind information not configured: {0}

Explanation
An error was detected while attempting to load default bind credentials. A field required to bind to LDAP was not configured. The returned exception text will contain the name of the required field.

System action
Processing stops.

User response
Ensure an appropriate ICTX profile is defined and the LDAPBIND class is active and RACLISTed. If the profile is updated, the LDAPBIND class must be RACLIST REFRESHed for the changes to become active.

ITY6528E  Error processing returned identity context. OidContext name size is not valid.

Explanation
A length inconsistency was detected in an internal identity context data structure.

System action
Processing stops.

User response
If the problem recurs, contact the IBM support center.

ITY6530E  Required LDAP bind information not configured: {0}

Explanation
An invalid data structure identifier (eyecatcher) was detected in an internal identity context data structure.

System action
Processing stops.

User response
If the problem recurs, contact the IBM support center.
Error processing returned identity context. OldContext version not valid.

**Explanation**
An invalid version was detected in an internal identity context data structure.

**System action**
Processing stops.

**User response**
If the problem recurs, contact the IBM support center.

---

Suffix `suffix_name` already in use. Remove duplicate suffix definition.

**Explanation**
The LDAP server reported that `suffix_name` was already defined as a suffix for another plugin or backend when ICTX plugin initialization attempted to register that name. The ICTX plugin must be defined with suffix “CN=ICTX”, which should not be used by any other plugin or backend in the configuration file. Neither should any subordinate suffix value in any letter case such as "cn=abc, cn=ictx" be defined. Also verify the ICTX configuration statement is not duplicated accidentally.

**System action**
ICTX plugin initialization fails. The LDAP server stops.

**User response**
Correct the configuration file statements and restart the LDAP server.

---

Failure encountered in the audit logging facility. R_auditx returned `saf_return_code`, `racf_return_code`, `racf_reason_code`.

**Explanation**
ICTX extended operations encountered a failure when invoking the audit logging facility. The R_auditx callable service returned the values `saf_return_code`, `racf_return_code`, and `racf_reason_code`.

**System action**
Initialization continues, but the remote auditing requests will fail until an administrator responds to the problem.

**User response**
If the remote auditing function is needed, correct the problem indicated by the R_auditx codes. R_auditx code set "8, 8, 4" indicates the user associated with the LDAP server does not have at least READ access to the FACILITY class profile IRR.RAUDITX.

---

Incorrect suffix configured for ICTX. Specify suffix "CN=ICTX" instead.

**Explanation**
ICTX extended operations encountered an error verifying configuration information. A suffix other than "CN=ICTX" was specified.
System action
ICTX extended operations initialization fails. The IBM TDS server stops.

User response
Ensure only the one "CN=ICTX" suffix is specified and restart the IBM TDS server.

ITY6597A Too many suffixes configured for ICTX. Specify only suffix "CN=ICTX".

Explanation
ICTX extended operations encountered an error verifying configuration information. More than one suffix was specified.

System action
ICTX extended operations initialization fails. The IBM TDS server stops.

User response
Ensure only the one "CN=ICTX" suffix is specified and restart the IBM TDS server.

ITY6598A ICTX suffix must be specified exactly once.

Explanation
ICTX extended operations encountered an error verifying configuration information. The required suffix "CN=ICTX" was not specified, or additional suffixes were specified.

System action
ICTX extended operations initialization fails. The IBM TDS server stops.

User response
Ensure only the one "CN=ICTX" suffix is specified and restart the IBM TDS server.

ITY6599E No suffix configured for ICTX. Specify suffix "CN=ICTX".

Explanation
ICTX extended operations encountered an error verifying configuration information. The required suffix "CN=ICTX" was not specified.

System action
ICTX extended operations initialization fails. The IBM TDS server stops.

User response
Ensure only the one "CN=ICTX" suffix is specified and restart the IBM TDS server.

ITY6598A No suffix configured for ICTX. Specify suffix "CN=ICTX".

Explanation
ICTX extended operations encountered an error verifying configuration information. The required suffix "CN=ICTX" was not specified.

System action
ICTX extended operations initialization fails. The LDAP server stops.

User response
Correct the ICTX suffix specification and restart the LDAP server.

ITY6599E Failure to update ICTX cache. R_cacheserv returned saf_return_code, racf_return_code, racf_reason_code.

Explanation
ICTX extended operations encountered a failure when attempting to store an entry in the cache. The R_cacheserv callable service returned the values saf_return_code, racf_return_code, and racf_reason_code.

System action
ICTX extended operations initialization fails. The LDAP server stops.

User response
Correct the ICTX suffix specification and restart the LDAP server.

ITY6599E Failure to update ICTX cache. R_cacheserv returned saf_return_code, racf_return_code, racf_reason_code.

Explanation
ICTX extended operations encountered a failure when attempting to store an entry in the cache. The R_cacheserv callable service returned the values saf_return_code, racf_return_code, and racf_reason_code.

System action
ICTX extended operations initialization fails. The LDAP server stops.

User response
Correct the ICTX suffix specification and restart the LDAP server.

ITY6599E Failure to update ICTX cache. R_cacheserv returned saf_return_code, racf_return_code, racf_reason_code.

Explanation
ICTX extended operations encountered a failure when attempting to store an entry in the cache. The R_cacheserv callable service returned the values saf_return_code, racf_return_code, and racf_reason_code.

System action
ICTX extended operations initialization fails. The LDAP server stops.

User response
Correct the ICTX suffix specification and restart the LDAP server.

ITY6599E Failure to update ICTX cache. R_cacheserv returned saf_return_code, racf_return_code, racf_reason_code.

Explanation
ICTX extended operations encountered a failure when attempting to store an entry in the cache. The R_cacheserv callable service returned the values saf_return_code, racf_return_code, and racf_reason_code.

System action
ICTX extended operations initialization fails. The LDAP server stops.

User response
Correct the ICTX suffix specification and restart the LDAP server.

ITY6599E Failure to update ICTX cache. R_cacheserv returned saf_return_code, racf_return_code, racf_reason_code.

Explanation
ICTX extended operations encountered a failure when attempting to store an entry in the cache. The R_cacheserv callable service returned the values saf_return_code, racf_return_code, and racf_reason_code.

System action
ICTX extended operations initialization fails. The LDAP server stops.

User response
Correct the ICTX suffix specification and restart the LDAP server.

ITY6599E Failure to update ICTX cache. R_cacheserv returned saf_return_code, racf_return_code, racf_reason_code.

Explanation
ICTX extended operations encountered a failure when attempting to store an entry in the cache. The R_cacheserv callable service returned the values saf_return_code, racf_return_code, and racf_reason_code.

System action
ICTX extended operations initialization fails. The LDAP server stops.

User response
Correct the ICTX suffix specification and restart the LDAP server.

ITY6599E Failure to update ICTX cache. R_cacheserv returned saf_return_code, racf_return_code, racf_reason_code.

Explanation
ICTX extended operations encountered a failure when attempting to store an entry in the cache. The R_cacheserv callable service returned the values saf_return_code, racf_return_code, and racf_reason_code.

System action
ICTX extended operations initialization fails. The LDAP server stops.

User response
Correct the ICTX suffix specification and restart the LDAP server.

ITY6599E Failure to update ICTX cache. R_cacheserv returned saf_return_code, racf_return_code, racf_reason_code.

Explanation
ICTX extended operations encountered a failure when attempting to store an entry in the cache. The R_cacheserv callable service returned the values saf_return_code, racf_return_code, and racf_reason_code.

System action
ICTX extended operations initialization fails. The LDAP server stops.

User response
Correct the ICTX suffix specification and restart the LDAP server.

ITY6599E Failure to update ICTX cache. R_cacheserv returned saf_return_code, racf_return_code, racf_reason_code.

Explanation
ICTX extended operations encountered a failure when attempting to store an entry in the cache. The R_cacheserv callable service returned the values saf_return_code, racf_return_code, and racf_reason_code.
Chapter 9. The eimadmin utility

The eimadmin utility is a z/OS UNIX System Services Shell tool. An administrator can use it to define an EIM domain and prime the domain with registries, identifiers, and associations between identifiers, registry users and policies. An administrator can also use eimadmin to give users (and other administrators) access to an EIM domain or list or remove the EIM entities.

An administrator can use the eimadmin command in two ways:
- By including information with command-line options on an eimadmin command
- By including information in an input file that an eimadmin command references

You can create the file manually or by exporting records from a database. (See “Using an input file” on page 129 for more information.) The administrator directs utility processing by specifying a combination of command-line options. (See “Purpose” on page 111 and “Parameters” on page 116 for more information.)

eimadmin

Purpose
Perform actions on the following objects:
- Domains
- Registries
- Identifiers
- Associations
- Access authorities
- Policies

The actions you can perform include the following:
- Add an object
- Purge an object
- List objects (for example, list directories, list registries, and so forth)
- Modify attributes associated with objects
- Erase attributes

Format

eimadmin -a | -p | -l | -m | -e
- -D | -R | -I | -A | -C | -Y
  [-b bindDN]
  [-B attribute]
  [-c accessType]
  [-d domainDN]
  [-E certificate]
  [-E accessUserType]
  [-F issuerFilter]
  [-g registryParent]
  [-G certificateFilterTemplate]
  [-h ldapHost]
  [-i identifier]
  [-j otherIdentifier]
  [-J subjectFilter]
  [-k URI]
  [-K keyFile [ -P keyFilePassword] [-N certificateLabel]]
Table 28 on page 113 summarizes the objects and actions and the flags required and optional for each.

Tips:

• Each eimadmin command must include one action and one object type. Depending on the object and action you are performing on it, EIM might require additional parameters.

• Some options are for multi-value attributes, which you can specify more than once. Other options are for single-value attributes, which you can specify once. (If you repeat an option that is for a single-value attribute, eimadmin processes only the first value it encounters in the command.) Other than this, the order in which you specify parameters is not important.

• You can code the parameters of the eimadmin command in several ways:
  – You can concatenate an action and an object, but must omit the embedded hyphen:
    
    -aD
  – You can include both hyphens but must separate the two options with a space:
    
    -a -D
  – In other words, the following is not valid because it includes both hyphens and there is no space before -D:
    
    -a-D

The following table summarizes required and optional flags for each object type and action pair. You can specify the value for most options in an input file instead of specifying it on the command line. See “Using an input file” on page 129 for more information. See Table 32 on page 132 for the mapping of file labels with command line options.

Rule:

The required connection flags, generally independent of the specified object type and action, are shown in Table 28 on page 113.

Parameters

Actions

-`a`|-`p`|-`l`|-`m`|-`e`
This is the action you want to perform:

- **-a**
  Add an object. (Create an object definition and its attributes.)

- **-p**
  Purge an object. (Remove an object definition and its attributes.)

- **-l**
  List an object. (Retrieve an object definition and its attributes.)

- **-m**
  Modify an attribute. (Alter an attribute of an existing object, either by changing a single-value attribute or adding a multi-value attribute.)

- **-e**
  Erase an attribute. (Clear a single-value attribute or remove a multi-value attribute.)

Object types

-`D`|-`R`|-`I`|-`A`|-`C`|-`Y`
This parameter specifies the object types on which to perform the action:

- **-D**
  A domain. This is a collection of identifiers, user registries, and associations between identifiers and user IDs, and policies, stored within an LDAP directory. (For more information about EIM domains, see “EIM domain” on page 6.)

- **-R**
  A registry. This is the name of a user registry. Associations are defined between identifiers and user IDs in the user registry. It is a logical collection of user identities and policies. (For more information, see “EIM domain” on page 6.)

- **-I**
  An identifier. This is the name of a person or entity participating in an EIM domain. (For more information, see “EIM domain” on page 6.)
-A  An association. This is a relationship between an identifier in the EIM domain with a user ID. (For more information, see “EIM domain” on page 6.)

-C  An access authority. This is an EIM-defined LDAP access control group. (For more information, see “EIM access control” on page 26.)

-Y  A policy. This is a relationship between a registry or domain and a user identity in a target registry.

**Processing controls, attributes, and connection values**

**Processing controls**
Processing controls include the following:

-s switch  
The `switch` specifies a value that affects the way the `eimadmin` utility functions operate. You can specify the following value:

RMDEPS  
Remove dependents when removing a domain or system registry. This facilitates removing a domain by first removing all identifiers and registries defined for the domain. It facilitates the removing a system registry by first removing all applications registries defined for the registry.

⚠️ **Attention:** The `eimadmin` utility does not warn you that dependents exist before removing them, so use this switch carefully.

-U identifierUUID  
The `identifierUUID` is the universally unique identifier form of the EIM identifier. This flag is only valid with `eimadmin -lI`.

-v verboseLevel  
The `verboseLevel` is an integer from 1 to 10, that controls the amount of trace detail that the `eimadmin` utility displays. (It is for diagnosing problems in the `eimadmin` utility.) The default value of 0 indicates no trace information. You can specify an integer value from 1 to 10, from the least to greatest amount of trace information.

The utility checks the value and displays trace information defined for the level and all lower levels. The following levels trigger specific information:

- "3", which indicates EIM API call parameters and return values
- "6", which indicates option values and input file labels
- "9", which indicates utility routine entry and exit statements

**Objects and attributes**

**Rule:** Options are single-valued unless indicated otherwise.

The section that follows explains required and optional attributes and their parameters.

**Tips:**

- You can specify these attributes as command options or as fields in input files. If you are specifying command options, you must enclose values with imbedded blanks within quotation marks (" or "). Quotation marks are optional for single-word values. Specifying a multi-word value without quotation marks in effect truncates the command line options; values after the first word are truncated.

- The following special characters are not allowed in `registryName`, `registryParent`, or `identifier`: 

  `, = + < > \ * 

**Rule:**
-B attribute
  The attribute flag is used to add, modify, remove, or clear and attribute for the domain. It may also enable or disable a function in the EIM domain.

  The attribute flag specified with the domain object may have the following value:
  POLICY
  Enable or disable default domain and registry policies. By default, default policies are disabled in the domain.

  The attribute flag specified with the registry object may have one of the following values:
  LOOKUP
  Enable or disable lookup operations
  POLICY
  Enable or disable default registry policies

  By default, registries are enabled for lookup operations, but default registry policies are disabled. Specifying -e deactivates the function. Specifying -m activates the function.

-c accessType
  The accessType specifies the scope of access authority that a user has over the EIM domain. It must be one of the following values:
  ADMIN
  Specifies administrative access.
  REGISTRY
  Specifies registry access. If you specify REGISTRY, you must also specify a registry value (-r). The registry value can be a specific registry name or it can be an asterisk (*) to indicate access to all registries.
  IDENTIFIER
  Specifies identifier access.
  MAPPING
  Specifies mapping operations access.

-E certificate
  The certificate flag is used to specify the source of a certificate. The name stored in the certificate will be used to create an association with an identifier. The certificate name may be DER or base 64 encoded. The base 64 encoded certificate may be in EBCDIC or ASCII.

  When working with an source, target, or administrative associations, the subject's distinguished name, the issuer's distinguished name, and the public key info are extracted from the certificate and used to create the registry user name for the association.

-f accessUserType
  The accessUserType specifies the type for the access user name. It must be one of the following:
  DN
  The accessUser is a distinguished name. (See -q accessUser for a description)
  KERBEROS
  The accessUser is a Kerberos identity. (See -q accessUser for a description)

-F issuerFilter
  All or part of the issuer portion of a certificate filter policy name. When used without the -E certificate flag, the issuer filter must be a sequence of relative distinguished names that make up a complete certificate filter policy issuer name. For example:
When used with the -E certificate flag, the issuer filter is a substring that indicates what part of the issuer's distinguished name from the certificate should be used for the certificate filter policy's issuer name. For example if the certificate has the issuer's distinguished name of the following:

```
OU=Certiﬁed User,O=A Certiﬁcate Authority,L=Internet
```

and the issuerFilter value is O=, then the issuer portion of the certificate filter policy name is:

```
O=A Certiﬁcate Authority,L=Internet
```

If the -F flag is omitted when working with certificate filter policies, the certificate filter policy's name will not contain an issuer filter.

**-G certificateFilterTemplate**

The name of a file or dataset containing an X.509 certificate. The name stored in the certificate will be used to create a certificate filter policy. The certificate may be DER or base 64 encoded. The base 64 encoded certificate may be in EBCIDIC or ASCII.

When working with a certificate filter policy, only the subject's distinguished name and issuer's distinguished name are extracted from the certificate. They are used as a template for the name of the certificate filter policy. The -J subjectFilter and -F issuerFilter flags are used to indicate what portion of the distinguished names to use.

**-g registryParent**

The registryParent specifies the name of a system registry. An application registry is a subset of a system registry. If you are adding an application registry, you must use the -r option and the -g option. The -r value is the application registry you are defining. The -g option is the preexisting system registry.

**-i identifier**

The identifier is a unique identifier name.

Example:

```
John Day
```

**-j otherIdentifier**

The otherIdentifier specifies a non-unique identifier name.

Example:

```
John
```

**Note:** You can specify this option multiple times to assign multiple non-unique identifiers.

**-J subjectFilter**

All or part of the subject portion of a certificate filter policy name. When used without the -E certificate flag, the subject filter must be a sequence of relative distinguished names that make up a complete certificate filter policy subject name. For example:

```
O=My Company,C=US
```

When used with the -E certificate flag, the subject filter is a substring that indicates what part of the subject's distinguished name from the certificate should be used for the certificate filter policy's subject name. For example if the certificate has the following subject distinguished name:

```
CN=John Smith,O=My Company,C=US
```

and the subjectFilter value is C=, then the subject portion of the certificate filter policy name is:

```
C=US
```

If the -J flag is omitted when working with certificate filter policies, the certificate filter policy name will not contain a subject filter.
The eimadmin utility

-k URI
The URI specifies the Universal Resource Identifier (URI) for the registry (if one exists).

-n description
The description specifies any text (that you provide) to associate with the domain, registry, identifier, or association.

Note: You can define a user description only for target associations.

-o information
The information specifies additional information to associate with an identifier or association.

Note: You can define user information only for target associations.
You can specify this option multiple times to assign multiple pieces of information.

-q accessUser
The accessUser specifies the user distinguished name (DN) or the Kerberos identity with EIM access, depending on the accessUserType specified.

-r registryName
The registryName specifies the name of a registry. When you add a new registry, eimadmin considers the registry a system registry unless you also specify the -g option. If you specify the -g option, eimadmin considers the registry an application registry.

-t associationType
The associationType specifies the relationship between an identifier and a registry or a policy type. It must be one of the following:

ADMIN
Indicates associating a user ID with an identifier for administrative purposes.

SOURCE
Indicates that the user ID is the source (or from) of a lookup operation.

TARGET
Indicates that the user ID is the target (or to) of a lookup operation.

DOMAIN
Indicates a default domain policy.

REGISTRY
Indicates a default registry policy.

FILTER
Indicates a certificate filter policy.

POLICY
Indicates any kind of policy.

Note: You can specify this option multiple times to define multiple relationships.

-T targetRegistryName
The targetRegistryName specifies the name of a registry. This value is used when creating or deleting a default registry policy.

-u registryUser
The registryUser specifies the user ID of the user defined in the registry.

-x registryAlias
The registryAlias specifies another name for a registry.
See “Working with registry aliases” on page 57 for information about working with aliases.
You can specify this option multiple times to assign multiple aliases.

-y registryType
The registryType specifies the type of registry. Predefined types that eimadmin recognizes include the following:

- RACF
You can also create your own types by concatenating a unique OID with one of the following two normalization methods:

- -caseIgnore
- -caseExact

(See “EIM registry definition” on page 11 for more information.)

-z registryAliasType
The registryAliasType specifies the type for a registry alias. You can invent your own value or use one of the following suggested values:

- DNSHostName
- KerberosRealm
- IssuerDN
- RootDN
- TCPIPAddress
- LdapDnsHostName

**Note:** For a set of command line options or single input data record, the eimadmin utility recognizes only the first specification of registryAliasType. However, the eimadmin utility does recognize multiple registry aliases and associates all of them with the single registryAliasType.

**Connection values**
The connection information needed by the utility includes the EIM domain (-d) and its controlling server (-h), the identity (-b,-w; or -K,-P,-N) with which to authenticate (bind) to the server, and the authentication method (-S).

For object types other than domain (-D), specifying the domain, server and bind identity is optional. If not specified, the information is retrieved from a RACF profile. See “Storing LDAP binding information in a profile” on page 62 for more information.

**Rule:** If any of the connect information is specified, the full set of values required for the connect type must be specified. Omitting one or more values (but not all) results in an error. Table 29 on page 122 shows the required and optional values for each connect and host type when specified with the eimadmin command:
Table 29: Required connection values

<table>
<thead>
<tr>
<th>Connection type</th>
<th>Host type secure(1daps://) / non-secure(1dap://)</th>
<th>Required values</th>
<th>Optional values</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIMPLE or CRAM-MD5</td>
<td>secure</td>
<td>-d, -h, -b, -w, -K, -P</td>
<td>-N</td>
</tr>
<tr>
<td></td>

<td>-N</td>
</tr>
<tr>
<td></td>
<td>non-secure</td>
<td>-d, -h, -S</td>
<td></td>
</tr>
</tbody>
</table>

Tips:

- Exceptions:
  - The domain option (-d) is not required for domain functions if the value is specified through an input file.
  - An SSL key database file password or stash file (-P) is not required when -K specifies a RACF key ring.
- The utility prompts for the simple bind password if required and -w is not specified on the command line, and prompts for the SSL key database file password if required and -P is not specified on the command line.

-S connectType
The connectType is the method of authentication to the LDAP server. It must be one of the following values:

- SIMPLE (bind DN and password)
- CRAM-MD5 (bind DN and protected password)
- EXTERNAL (digital certificate)
- GSSAPI (Kerberos)

If not specified, the connect type defaults to SIMPLE.

For connect type GSSAPI, the default Kerberos credential is used. This credential must be established using a service such as kinit prior to running eimadmin. For kinit and related information, refer to z/OS Integrated Security Services Network Authentication Service Administration.

-d domainDN
The domainDN is the full distinguished name (DN) of the EIM domain. It begins with 'ibm-eimDomainName='. It further consists of:

- domainName — The name of the EIM domain you are creating, for example: MyDomain
- parent distinguished name — The distinguished name for the entry immediately preceding the given entry in the directory information tree hierarchy, for example, "o=ibm,c=us".

Example:

```
ibm-eimDomainName=MyDomain,o=ibm,c=us
```

-h ldapHost
The ldapHost is the URL and port for the LDAP server controlling the EIM data. The format is:
Examples:

- **ldap://**some.ldap.host:389
- **ldaps://**secure.ldap.host:636

**-b bindDN**  
The **bindDN** is the distinguished name to use for the simple bind to LDAP. The format is:

Examples:

- cn=Johns Admin  
  or  
  - cn=Johns Admin,o=ibm,c=us

**-w bindPassword**  
The **bindPassword** is the password associated with the bind DN (for the LDAP bind).

**-K keyFile**  
The **keyFile** is the name of the SSL key database file, including the full path name. If the file cannot be found, it is assumed to be the name of a RACF key ring which contains authentication certificates. This value is required for SSL communications with a secure LDAP host (prefixed ldaps://).

Example:

- /u/eimuser/ldap.kdb

**-P keyFilePassword**  
The keyFilePassword is the password required to access the encrypted information in the key database file. Alternatively, you can specify an SSL password stash file for this option by prefixing the stash file name with file://.

Example:

- secret  
  or  
  - file:///u/eimuser/ldapclient.sth

**Note:** The eimadmin utility prompts for a key file password if you specify the name of a key database file for -K but not the -P option on the command line.

**-N certificateLabel**  
The **certificateLabel** identifies which certificate to use from the key database file or RACF key ring. If this option is not specified, the certificate marked as the default in the file or ring is used.

Example:

- eimcert

**Authorization**

The LDAP administrator has the authority to use the eimadmin utility and access to all the functions it provides. EIM administrators can use the utility as long as:

- They have a bind distinguished name and password defined at the LDAP server containing the EIM domain
- Their bind distinguished name has one of the EIM authorities:
  - EIM administrator  
  - EIM registries administrator
The eimadmin utility

- EIM registry X administrator
- EIM identifiers administrator

See “EIM access control” on page 26 for details about the specific tasks each administrator can perform.

Messages

Eimadmin issues a message to prompt for a password or to indicate an error. Do not expect to receive a message for successful completion unless you use an input file. When processing records in an input file, eimadmin issues an informational message for the start, stop, and a progress message for every 50 records.

Note: Eimadmin returns one or more data lines for list (-l) requests unless it finds no matching EIM entries or the bind identity is not authorized to that data.

For eimadmin error messages, see Chapter 8, “Messages,” on page 77, specifically ITY4xxx messages.

Error codes

The eimadmin utility returns one of the following exit codes upon completion:

<table>
<thead>
<tr>
<th>Exit code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No errors encountered.</td>
</tr>
<tr>
<td>4</td>
<td>One or more errors encountered but, if you specified an input file, all records were processed.</td>
</tr>
<tr>
<td>8</td>
<td>A severe error occurred that caused processing to stop before reaching the end of an input file, if specified.</td>
</tr>
</tbody>
</table>

Examples for working with policies

Creating an x.509 registry

The following creates an x.509 registry:

```bash
eimadmin -aR -h ldap://my.server
   -b "cn=EIM admin,o=My Company,c=US" -w secret
   -d "ibm-eimDomainName=My Employees,o=My Company,c=US"
   -r myCertificateMappings -y X509
```

Enabling or disabling a registry for lookup or policy operations

A registry may be enabled for lookup operations by using the -mR action and -B LOOKUP flag. The policies in a registry may be enabled by using -B POLICY with the -mR action. For example:

```bash
eimadmin -mR -h ldap://my.server
   -b "cn=EIM admin,o=My Company,c=US" -w secret
   -d "ibm-eimDomainName=My Employees,o=My Company,c=US"
   -r myCertificateMappings -B POLICY
```

A registry disabled for lookups by using -B LOOKUP with the -eR action. The policies in a registry may be disabled by using -B POLICY with the -eR action. By default lookups are enabled and policies are disabled.

Enabling or disabling a domain's use of policies

```bash
eimadmin -mD -h ldap://my.server
   -b "cn=EIM admin,o=My Company,c=US" -w secret
```
Policies may be disabled for a domain by using the -eD action and -B POLICY flag. By default, policies in a domain are disabled. Domains are always enabled for lookup operations.

Creating an association using the name stored within a certificate

This examples assumes the certificate contains the following subject’s and issuer’s distinguished names:

SDN: CN=John Day, O=My Company, C=US
IDN: OU=Certified User, O=A Certificate Authority, L=Internet

eimadmin -AA -h ldap://my.server
  -b "cn=EIM admin,o=My Company,c=US" -w secret
  -d "ibm-eimDomainName=My Employees,o=My Company,c=US"
  -i "John Day"
  -r myCertificateMappings -E certificate
  -t admin

Listing an association that was created using a certificate

eimadmin -IA -h ldap://my.server
  -b "cn=EIM admin,o=My Company,c=US" -w secret
  -d "ibm-eimDomainName=My Employees,o=My Company,c=US"
  -i "John Day" -t admin

This produces output such as the following:

unique identifier: John Day
association: ADMIN
registry: myCertificateMappings
registry type: X509
registry user: <SDN>CN=John Day,O=My Company,C=US</SDN>OU=VeriSign Class 1 Individual Subscriber,O=A Certificate Authority,L=Internet</IDN><HASH_VAL>34238b120e3675f912e3d68495847392017632ac</HASH_VAL>

Removing an association using the name stored within a certificate

This examples assumes the certificate contains the following subject’s and issuer’s distinguished names:

SDN: CN=John Day, O=My Company, C=US
IDN: OU=Certified User, O=A Certificate Authority, L=Internet

eimadmin -PA -h ldap://my.server
  -b "cn=EIM admin,o=My Company,c=US" -w secret
  -d "ibm-eimDomainName=My Employees,o=My Company,c=US"
  -i "John Day"
  -r myCertificateMappings -E certificate
  -t admin

If you don’t have the original certificate, another approach to removing an association involving a certificate user name is to copy the registry user name from the output of a list association and provide it with the -u flag. For example:

eimadmin -PA -h ldap://my.server
  -b "cn=EIM admin,o=My Company,c=US" -w secret
  -d "ibm-eimDomainName=My Employees,o=My Company,c=US"
  -i "John Day"
  -r myCertificateMappings
  -u "<SDN>CN=John Day,O=My Company,C=US</SDN>"\"<IDN>OU=VeriSign Class 1 Individual Subscriber,O=A Certificate Authority,L=Internet</IDN><HASH_VAL>34238b120e3675f912e3d68495847392017632ac</HASH_VAL>"
  -t admin

Creating a domain policy

eimadmin -aY -h ldap://my.server
  -b "cn=EIM admin,o=My Company,c=US" -w secret
The eimadmin utility

Listing the domain policy

eimadmin -lY -h ldap://my.server
- b "cn=EIM admin,o=My Company,c=US" - w secret
- d "ibm-eimDomainName=My Employees,o=My Company,c=US"
- T zOSRegistry - u DAY
- t domain

This produces output such as the following:

domain name: My Employees
  policy type: DOMAIN
  target registry: zOSRegistry
  target registry user: DAY
  domain policies: ENABLED
  target registry lookups: ENABLED
  target registry policies: DISABLED

Deleting a domain policy

eimadmin -pY - h ldap://my.server
- b "cn=EIM admin,o=My Company,c=US" - w secret
- d "ibm-eimDomainName=My Employees,o=My Company,c=US"
- T zOSRegistry - u DAY
- t domain

Creating a registry policy

eimadmin -aY -h ldap://my.server
- b "cn=EIM admin,o=My Company,c=US" - w secret
- d "ibm-eimDomainName=My Employees,o=My Company,c=US"
- r zOSRegistry - T OS400Registry - u JOHNDAY
- t registry

Listing a registry policy

eimadmin -lY -h ldap://my.server
- b "cn=EIM admin,o=My Company,c=US" - w secret
- d "ibm-eimDomainName=My Employees,o=My Company,c=US"
- r zOSRegistry
- t registry

This produces output such as the following:

  source registry: zOSRegistry
  policy type: REGISTRY
  target registry: OS400Registry
  target registry user: JOHNDAY
  domain policies: ENABLED
  source registry lookups: ENABLED
  target registry lookups: ENABLED
  target registry policies: DISABLED

Deleting a registry policy

eimadmin -pY - h ldap://my.server
- b "cn=EIM admin,o=My Company,c=US" - w secret
- d "ibm-eimDomainName=My Employees,o=My Company,c=US"
- r zOSRegistry - T OS400Registry - u JOHNDAY
- t registry
Creating a filter policy

This example assumes the file certificate contains the following subject’s and issuer’s distinguished names:

| SDN: | CN=John Day,O=My Company,C=US |
| IDN: | OU=Certified User,O=A Certificate Authority,L=Internet |

```
```

or

```
eimadmin -aY -h ldap://my.server -b "cn=EIM admin,o=My Company,c=US" -w secret -d "ibm-eimDomainName=My Employees,o=My Company,c=US" -r myCertificateMappings -G certificate -J O= -F OU= -T OS400Registry -u JOHNDAY -t filter
```

A filter policy with the full subject's and issuer's distinguished names can be created using just the certificate template. For example:

```
eimadmin -aY -h ldap://my.server -b "cn=EIM admin,o=My Company,c=US" -w secret -d "ibm-eimDomainName=My Employees,o=My Company,c=US" -r myCertificateMappings -G certificate -T OS400Registry -u JOHNDAY -t filter
```

Listing the filter policy association

```
```

or

```
eimadmin -1Y -h ldap://my.server -b "cn=EIM admin,o=My Company,c=US" -w secret -d "ibm-eimDomainName=My Employees,o=My Company,c=US" -r myCertificateMappings -G certificate -J O= -F OU= -t filter
```

This produces output such as the following:

```
source registry: myCertificateMappings
  policy type: FILTER
  target registry: OS400Registry
  target registry user: JOHNDAY
  domain policies: ENABLED
  source registry lookups: ENABLED
  target registry lookups: ENABLED
  target registry policies: DISABLED
```
Deleting a filter policy

eimadmin -pY -h ldap://my.server -b "cn=EIM admin,o=My Company,c=US" -w secret
-d "ibm-eimDomainName=My Employees,o=My Company,c=US"
-r myCertificateMappings
-J "O=My Company,C=US"
-F "OU=Certified User,O=A Certificate Authority,L=Internet" -T OS400Registry
-u JOHNDAY -t filter

or:

eimadmin -pY -h ldap://my.server
-b "cn=EIM admin,o=My Company,c=US" -w secret
-d "ibm-eimDomainName=My Employees,o=My Company,c=US"
-r myCertificateMappings -T OS400Registry -u JOHNDAY
-G certificate -J O= -F OU=
-t filter

Examples for listing various objects without an input file

• List a single domain by entering a command such as the following:

  eimadmin -lD -h ldap://my.server -b "cn=EIM admin,o=My Company,c=US"
  -d "ibm-eimDomainName=My Employees,o=My Company,c=US"

This produces output such as the following:

domain name: My Employees
domain DN: ibm-eimDomainName=My Employees,o=My Company,c=US
description: employees in my company
policies: DISABLED
version: 2

• List a single registry by entering a command such as the following:

  eimadmin -lR -r MyRegistry

This produces output such as the following:

registry: MyRegistry
registry kind: APPLICATION
registry parent: MySystemRegistry
registry type: RACF
description: my racf registry
URI: ldap://some.big.host:389/profileType=User,cn=RACFA,o=My Company,c=US
registry alias: TCPGROUP
registry alias type: DNSHostName
lookups: DISABLED
policies: DISABLED

Another example is:

  eimadmin -lR -h ldap://my.server
  -b "cn=EIM admin,o=My Company,c=US" -w secret
  -d "ibm-eimDomainName=My Employees,o=My Company,c=US"
  -r myCertificateMappings

This produces output such as the following:

registry: myCertificateMappings
registry kind: SYSTEM
registry type: X509
lookups: DISABLED
policies: DISABLED

• List identifiers by entering a command such as the following:

  eimadmin -lI -h ldap://my.server
  -b "cn=EIM admin,o=My Company,c=US" -w secret
This produces output such as the following:

<table>
<thead>
<tr>
<th>unique identifier: J.C.Smith</th>
</tr>
</thead>
<tbody>
<tr>
<td>identifier UUID: d1284038asdfs1kae8-1395adfj379423294d</td>
</tr>
<tr>
<td>other identifier: J.C.Smith</td>
</tr>
<tr>
<td>other identifier: Joseph</td>
</tr>
<tr>
<td>other identifier: Joe</td>
</tr>
<tr>
<td>description: 004321</td>
</tr>
<tr>
<td>information: 001</td>
</tr>
<tr>
<td>information: 1990-04-11</td>
</tr>
</tbody>
</table>

- List an identifier using the identifier's UUID by entering a command such as the following:

```
eimadmin -lI -h ldap://my.server
-b "cn=EIM admin,o=My Company, c=US" -w secret
-d "ibm-eimDomainName=My Employees,o=My Company, c=US"
-U "d1284038asdfs1kae8-1395adfj379423294d"
```

This produces output such as the following:

d1284038asdfs1kae8-1395adfj379423294d J.C.Smith

- List target associations by entering a command such as the following:

```
eimadmin -lA -h ldap://my.server
-b "cn=EIM admin,o=My Company, c=US" -w secret
-d "ibm-eimDomainName=My Employees,o=My Company, c=US"
-i "J.C.Smith" -t target
```

This produces output such as the following:

<table>
<thead>
<tr>
<th>unique identifier: J.C.Smith</th>
</tr>
</thead>
<tbody>
<tr>
<td>identifier UUID: d1284038asdfs1kae8-1395adfj379423294d</td>
</tr>
<tr>
<td>registry: MyRegistry</td>
</tr>
<tr>
<td>registry type: RACF</td>
</tr>
<tr>
<td>association: target</td>
</tr>
<tr>
<td>registry user: SMITH</td>
</tr>
<tr>
<td>description: TSO</td>
</tr>
<tr>
<td>information: 1989-08-01</td>
</tr>
<tr>
<td>information: ADMIN1</td>
</tr>
</tbody>
</table>

- List accesses by entering a command such as the following:

```
eimadmin -lC -c admin
```

This produces output such as the following:

<table>
<thead>
<tr>
<th>access user: cn=JoeUser,o=My Company, c=us</th>
</tr>
</thead>
<tbody>
<tr>
<td>access user: cn=admin1,o=My Company, c=us</td>
</tr>
<tr>
<td>access user: cn=admin2,o=My Company, c=us</td>
</tr>
</tbody>
</table>

### Using an input file

You can use the `eimadmin` command to add objects and associated attribute values to an EIM domain by specifying command-line options or specifying an input file name.

**Tip:** The advantage of using a file to add information such as associated attributes to an EIM domain is that you can input any number of entities of the same type with a single call to `eimadmin`. For example, you might want define a large number of identities that correspond to users in a platform-specific database such as RACF.

You can create your input file manually or export it from a database. For example, you can use `IRRDBU00` to extract records from the RACF database.
The `eimadmin` utility

**Tip:** To pass the input file to `eimadmin`, use UNIX standard input (`stdin`).

The `eimadmin` utility interprets the data in the input file according to the command line options you specify on an `eimadmin` command. For instance, if you use the `-aI` option combination, this directs `eimadmin` to look for identifier information within the file and add it to the EIM domain.

**Input file requirements**

The `eimadmin` requirements for the input file and its records include the following:

- The file must be sequential.
- By convention, each file line consists of a single record. (Only one record is allowed per file line. Records cannot span lines.)
- Records have a maximum length of 10,000 characters.
- Records contain column-delimited fields. (The label line defines these fields. See “The label line” on page 131 for more information.) The fields of each record contain character values representing a single object and optional associated attributes.

**Tip:** If you are using an input file to add identifiers, each record should contain a value that can serve as a unique EIM identifier for the user. IBM recommends that you sort the records by the field that is unique. This unique identifier might be an employee name or number, but it is unlikely to be the user ID for a registry. The identifier chosen must be unique within the EIM domain because associated user IDs cannot be unique across multiple registries.

If you have previously populated your EIM domain with unique identifiers, the unique identifiers for which you are adding associations or attributes in your input records should match these unique identifiers.

After you sort the records by the unique identifier fields, check the results to verify that non-blank values appear in this field for each record and that the values are not duplicated (unless this is intentional). The `eimadmin` utility generates an error each time it tries to add an object that has been previously defined.

**Input file contents**

The file can include:

- Comments; to include a comment line, use "#" as the first non-blank character in the line.
  
  **Note:** The `eimadmin` utility ignores blank lines and comment lines.

- Upper and lower case (The `eimadmin` utility preserves letter case.)

- Blanks (Whitespace is any combination of blanks, tabs, and other 'invisible' control characters.
  
  **Note:** Avoid using whitespace characters other than blanks because the `eimadmin` utility does not consider them when it performs positional parsing. The `eimadmin` utility truncates leading and trailing whitespace within fields when it is parsing input values. The `eimadmin` utility does not process anything in a field that contains all whitespace.)

<table>
<thead>
<tr>
<th>EBCDIC Hexadecimal value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>05</td>
<td>HT — tab</td>
</tr>
<tr>
<td>0B</td>
<td>VT — vertical tab</td>
</tr>
<tr>
<td>0C</td>
<td>FF — form feed</td>
</tr>
<tr>
<td>0D</td>
<td>CR — carriage return</td>
</tr>
</tbody>
</table>
The label line

The first non-blank, non-comment line in the input file must be the label line. This consists of one or more labels that identify starting and ending positions for column-delimited fields in subsequent lines. For details about names of labels, see Table 32 on page 132.

Example

Suppose you want to input employee records of last name, first name, and employee number. Your data might look like the information in the following grid. (The header lines of the grid are not part of the data and are there simply to show column numbers):

|   | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 |
|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | B | l | a | c | k | s | t | o | n | e | A | u | g | u | s | t | i | n | e |
| 0 | 0 | 0 | 2 | 1 | 7 | 3 | 4 | B | r | a | d | y |   |   | B | a | r | b | a | r | a |
| 0 | 0 | 0 | 3 | 1 | 1 | 2 | 4 | L | l | o | y | d |   |   | C | a | r | o | l |
| 0 | 0 | 0 | 4 | 1 | 7 | 4 | 5 | M | a | r | t | i | n | s | o | n |   | D | e | b | b | i | e |

(The record is 30 characters long. The first four slots are a four-digit sequence number followed by a blank. The employee numbers start in column 6 and end in column 10. The last names start in column 11 and end in column 20. The first names start in column 22 and end in column 30.)

Your label line would look like the following:

|   | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 |
|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|   | I | U |   |   |   |   | U | N |   | I | N |   |   |   |   |   |   |   |

The labels in the preceding label line are:

- "IU" represents a unique identifier (employee number)
- "UN" represents the registry user name (last name)
- "IN" represents a non-unique identifier (first name)

These labels mark the starting positions of the fields for employee number, last name, and first name. The semicolons mark the ending positions for these fields. See “Example for adding a list of identifiers to an EIM domain” on page 134 for a more complex example.

Example — Using eimadmin with the tabular output of SMF Unload

The audit records cut by EIM contain the UUID of identifiers and policies. eimadmin can be used to get the friendly name associated with the UUID.

First, generate the tabular output using SMF Unload. The edit the tabular output so that the 'UU' label appears above the UUID. For this example, assume the data is in the HFS file smfdata.

Then run the following eimadmin command:

```
eimadmin -lI -h ldap://my.server -b "cn=EIM admin,o=My Company, c=US" -d "ibm-eimDomainName=My Employees,o=My Company, c=US" -w secret <smfdata
```

The output from the eimadmin command will list a mapping between the UUIDs and the unique identifiers.
Summary of associated labels

Now that you have seen an example of a few of the labels, it is time to look at a comprehensive list of the labels. The following table summarizes the labels associated with object types and command line options associated with these labels.

<table>
<thead>
<tr>
<th>Object Types</th>

</tbody>
</table>

**Rules:** Here are the rules for creating a label line:

- Indicate the start of each field by putting a label (from column two of Table 32 on page 132) in the starting column position. Indicate the end of each field by putting a semicolon in the ending column position.
- Separate labels and semicolons with zero or more blanks. (Do not use other white-space characters, such as tabs, because eimadmin interprets them as single blank characters, so a record that visually appears to have correct column positioning might be incorrect for processing.)
- You can specify multi-value labels more than once; for a multi-value label, each value is considered for processing. If you specify more than one value for a single-value label, eimadmin processes only the first value you specify. (See the Description column of Table 32 on page 132 for information about which labels are multi-value.)

**Processing differences between command-line options and input files**

If you specify information both as command-line options and with an input file, command-line values have priority over input file values. As previously discussed, a single-value option can have only one value. If you specify more than one value, eimadmin processes only the first value. A multi-value option can have more than one value. If you specify more than one value, eimadmin processes all of these values.

If you specify information for a single-value option both within a command and in an input file, eimadmin processes the information on the command rather than that in the file. (This is assuming the value is relevant to the object type and action combination that you specify.)

**Note:** However, if you specify information for a multi-value option both in a command and in a file, eimadmin processes all the values, processing those in the command first. The eimadmin utility ignores command line options or input file labels that are not appropriate for the object type and action combination that you specify.

**The output file**

The eimadmin utility generates messages to stdout to indicate the following:
The eimadmin utility

- The eimadmin utility version the date and start time, and command options and parameters (as shown in the following example line. See Step “3” on page 135 for the full example)

```
ITY4020 eimadmin (v1) started Mon May 20 10:50:58 2002 with options eimadmin -I
```

- If called to list objects or attributes, the requested information retrieved from the EIM domain
- Whether processing ended normally or stopped due to error
- A summary of processed records (successful and unsuccessful)

The error file

If any errors occur during processing, the eimadmin utility generates error messages to stderr. Failing records are echoed to the output in their entirety. You can correct the failing records and rerun them through the utility. See Chapter 12, “EIM header file and example,” on page 367 for a sample error file.

Example for adding a list of identifiers to an EIM domain

1. Create a file named 'employees.txt' containing identity information in a format similar to the following:

```plaintext
# Sample eimadmin input file
#    User id Birth      Type   Created       First    Nickname  Full       Dept              Hire       Empl
#              date            by             name               name                         date       num

UN     ;UI       ; UD    ;UI     ;        IN     ; IN       ;IU        ;    II  ;         II       ; ID   ;
021P SMITH   1959-08-01 TSO    ADMIN1  NO  NO  Joseph   Joe       J.C.Smith  DEPTD01  14:20:16 1990-04-11 004321
022P JONES   1968-05-03 TSO    ADMIN1  NO  NO  Robert   Bob       R.Z.Jones  DEPTD01  16:01:57 1988-02-16 001234

```

Note:

a. The exported database can contain information that the eimadmin utility does not use. The two columns with "NO" and the column with times between the two II values are such information.
b. There can be only one UN (registry user name), UD (user description), IU (unique identifier), and ID (identifier description).
c. There can be multiple values for UI, IN, and II (user information, non-unique identifier, and identifier information, respectively).

2. Add the identifiers by using the following eimadmin command:

```
eimadmin
-aI
-h ldap://my.server
-b "cn=EIM admin,o=My Company, c=US"
-d "ibm-eimDomainName=My Employees,o=My Company, c=US" < employees.txt
> addemployees.out 2> addemployees.err
```

Note: Since the -w flag was omitted, the issuer of the eimadmin command is prompted for the password.

If the unique identifiers were not previously defined, the output file is the following:

```
ITY4020 eimadmin (v1) started Mon May 20 10:50:58 2002
eimadmin
-aI
-h ldap://my.server
-b "cn=EIM admin,o=My Company, c=US"
-d "ibm-eimDomainName=My Employees,o=My Company, c=US"
ITY4022 6 records processed -- 4 successful; 2 failed.
ITY4021 Processing ended normally.
```
The error file addemployees.err contains the following:

```
ITY4030 Service eimAddIdentifier() returned error 117 -- ITY0019 EIM identifier already exists by this name.
ITY4028 Error occurred while processing input line 9.
023F JONES2 1985-10-15 BATCH ADMIN4 NO NO Robert R.Z.Jones DEPTD01 14:12:20 1988-02-16 001234
ITY4012 Unique identifier not specified.
ITY4028 Error occurred while processing input line 11.
025F BROWN 1990-04-11 TSO ADMIN3 NO NO Charles Chuck DEPTD01 09:47:57 1995-01-10 003210
```

3. List the identifiers using the same input file by entering the following command:

```
eimadmin
 -ll
 -h ldap://my.server
 -b "cn=EIM admin,o=My Company, c=US"
 -d "ibm-eimDomainName=My Employees,o=My Company, c=US" < employees.txt
 > listids.out 2> listids.err
```

The file listids.out contains output such as the following:

```
ITY4020 eimadmin (v1) started 2001/10/30 at 15:09:00 with options eimadmin -ll
 -h ldap://my.server -b "cn=EIM admin,o=My Company, c=US"
 -d "ibm-eimDomainName=My Employees,o=My Company, c=US"

unique identifier: J.C.Smith
other identifier: J.C.Smith
other identifier: Joseph

```

```
ITY4022 6 records processed -- 6 successful; 0 failed.
ITY4021 Processing ended normally.
```

While a unique identifier is required for the add action, the eimadmin list action accepts a non-unique identifier when a unique identifier is not provided. The utility searches for entries with the non-unique identifier 'Charles', the first non-unique identifier that appears in the data line. No list output is returned for this line because no matches are found in the domain.

**Note:**
a. Notice that the entry for 'R.Z.Jones' is duplicated in the list output. This occurs because there are
two data lines with the same unique identifier. The utility processes each line separately, in order of
appearance, without recognizing similarities between them.

b. Also notice within each identifier entry that a non-unique value ("other identifier") duplicates the
unique identifier value. This is the manner in which the information is stored in LDAP. Do not
attempt to remove the duplicate value.

4. You might want to create a number of default registry policies or certificate filter policies using the eim
admin input file capability. The following example creates default registry policies for three registry:
REG1, REG2, and REG3X509. The following input file, registryPolicies defines the default policies:

```
# default registry policies for REG1, REG2, and REG3X509
# RS - Source registries
# RG - Target registries
# UN - User names in the target registries
# PT - Policy type
#    RS ;    RG        ;   UN     ;          PT      ;
REG1       REG2       PUBLIC        REGISTRY
REG1       REG3X509   PUBLIC        REGISTRY
REG2       REG1       PUBLIC
REG2       REG3X509   PUBLIC        REGISTRY
REG3X509   REG1       PUBLIC              REGISTRY
REG3X509   REG2       PUBLIC        REGISTRY
```

and the following command will cause the updates to be made to the EIM domain:

```
eimadmin -aY -d ibm-eimDomainName=My Employees, o= My Company, c=US -h ldap://my.server -b "cn=EIM admin,o=My Company,c=US" -w secret < registryPolicies
```

The REG3X509 registry is an X509 registry so a number of certificate filter policies are defined as well.
The following input file, registryFilterPolicies defines the default certificate filter policies:

```
# default certificate filter policies for an X509 registry
# RS - Source registry
# FI - Issuer's filter value
# RG - Target registry
# UN - User name in the target registry
# PT - Policy type
#    RS ;     FI                                    ; RG      ;        UN        ;
#    PT       ;
REG3X509     C=US                                    REG1      PUBLIC      FILTER
REG3X509     C=US                                    REG2      PUBLIC      FILTER
REG3X509     O=A Certificate Authority, L=Internet   REG1      PUBLIC      FILTER
REG3X509     O=A Certificate Authority, L=Internet   REG2      PUBLIC      FILTER
```

and the following command will cause the updates to be made to the EIM domain:

```
eimadmin -aY -d ibm-eimDomainName=My Employees, o= My Company, c=US -h ldap://my.server -b "cn=EIM admin,o=My Company,c=US" -w secret < registryFilterPolicies
```

Before the policies take effect, the domain and registries must have policies enabled. The following
command will enable policies at the domain level:

```
eimadmin -mD -B POLICY -d ibm-eimDomainName=My Employees, o= My Company, c=US -h ldap://my.server -b "cn=EIM admin,o=My Company,c=US" -w secret
```

Another input file, registryEnable, can be used to enable policies for each registry in the domain:

```
# enable the policies in the registries
# RN - Registry name
# RB - Registry attribute
#    RN ;     RB ;
REG1      POLICY
```
and the following command will make the updates to the registries:

```bash
eimadmin -mR -d ibm-eimDomainName=My Employees, o= My Company, c=US -h ldap://my.server -b "cn=EIM admin,o=My Company,c=US" -w secret < registryEnable
```

5. Associations between identifiers and certificates can be created by using the input file capability of eimadmin. In this example, the current directory contains three files with the certificates of three users. The input file, certMappings contains the information required to define the relationships with EIM identifiers:

```plaintext
# Mappings between identifiers and certificates in files
# IU - Unique identifier
# UC - Certificate file name containing the user's certificate
IU    ;       UC   ;
John Day    ./JohnDayCert
Jill Jack   ./JillJackCert
Jane Day    ./JaneDayCert
```

By issuing the following command, the source associations between the users name in the certificates and their EIM identifiers will be added to the domain:

```bash
eimadmin -aA -r REG3X509 -s SOURCE -d ibm-eimDomainName=My Employees, o= My Company, c=US -h ldap://my.server -b "cn=EIM admin,o=My Company,c=US" -w secret < certMappings
```

**Note:** In order for this to work, the registry must have a registry type of X509.

**Using eimadmin with the tabular output of SMF Unload**

The audit records cut by EIM contain the UUID of identifiers and policies. eimadmin can be used to get the friendly name associated with the UUID.

First, generate the tabular output using SMF Unload. Then edit the tabular output so that the 'UU' label appears above the UUID. For this example, assume the data is in the HFS file smfdata.

Then run the following eimadmin command:

```bash
eimadmin -lI -h ldap://my.server -b "cn=EIM admin,o=My Company, c=US"
-d "$ibm-eimDomainName=My Employees,o=My Company,c=US" -w secret
<smfdata
```

The output from the eimadmin command will list a mapping between the UUIDs and the unique identifiers.
Chapter 10. EIM Auditing

Auditing is an important part of keeping your enterprise secure. Applications which allow you to use user ID mappings must be kept secure to locate an end user's identity on a server system and trust that the end user has been correctly authenticated at the client. This means that the data mapped via EIM must be kept accurate and secure. To facilitate this, EIM allows you to perform auditing functions on select EIM APIs.

Auditing EIM events

Existing RACF commands are used to identify what events to log and when to log them. The EIM audit log records are written to SMF as type-83 subtype 2 records. Authentication and authorization failures are displayed on the security console and stored in the caller's job log. The SMF type-83 log records containing EIM events can be unloaded using the RACF SMF Data Unload utility for further analysis by auditing tools.

Categories of EIM events

EIM events are divided into three groups of resources:

- EIM Connect (including disconnects)
- EIM Admin
- EIM Lookup

Each group of events is qualified by whether or not the specific API was successful, if it failed because of an authentication or authorization failure, or if the data was not found. The controls a security administrator or auditor can use to implement a security policy are defined using grouping of events as well. Each group of events is controlled by a resource in the RAUDITX class. A profile in the RAUDITX class can be defined with the appropriate auditing options. The resources are:

- EIM.domain name.CONNECT
- EIM.domain name.ADMIN
- EIM.domain name.LOOKUP

Some events always cause a log record to be written. For example, attempts to connect with an EIM domain controller that fail because the bind user could not be authenticated.

<table>
<thead>
<tr>
<th>Resource in the RAUDITX class</th>
<th>Events</th>
</tr>
</thead>
<tbody>
<tr>
<td>EIM.domain name.CONNECT</td>
<td>Connects, disconnects with an EIM domain controller</td>
</tr>
<tr>
<td>EIM.domain name.ADMIN</td>
<td>All loggable EIM administration tasks, such as creating, deleting, modifying, or listing domains, identifiers, associations, and policies</td>
</tr>
<tr>
<td>EIM.domain name.LOOKUP</td>
<td>EIM lookup operations that retrieve mappings from an EIM domain, such as eimGetTargetFromSource, eimGetTargetFromIdentifier, or eimGetAssociatedIdentifiers</td>
</tr>
</tbody>
</table>

Profiles can be defined in the RAUDITX class that can apply to all events or a subset.
### Table 34: Covering profiles in the RAUDITX class and descriptions

<table>
<thead>
<tr>
<th>Profile</th>
<th>Events</th>
</tr>
</thead>
<tbody>
<tr>
<td>EIM.*</td>
<td>All EIM events, all domains</td>
</tr>
<tr>
<td>EIM.domain.name.*</td>
<td>All EIM events in a particular domain</td>
</tr>
<tr>
<td>EIM.domain.name.CONNECT</td>
<td>All attempts to bind/unbind with a particular domain; bind failures are always logged</td>
</tr>
<tr>
<td>EIM.domain.name.ADMIN</td>
<td>All admin events with a particular domain</td>
</tr>
<tr>
<td>EIM.domain.name.LOOKUP</td>
<td>All lookup events with a particular domain</td>
</tr>
</tbody>
</table>

The domain name used in the resource name and RACF profile is the same as the EIM domain name with the following differences:

- all blanks, commas, parenthesis, semicolons, asterisks, percent signs, and ampersands are removed
- the compressed name is truncated if it exceeds 234 characters
- lowercase characters are treated the same as uppercase

Generics must be active for the RAUDITX class before the profiles EIM.* and EIM.domain.name.* profiles are created. Use the SETROPTS GENERIC(RAUDITX) command to activate generics.

The log records that are generated can be extracted from the SMF dataset by using the RACF SMF Data Unload tool to convert the logged data into a format that can be analyzed using a relational database manager or a tool like DFSORT ICETOOL or into an XML document.

Each EIM API belongs to one of these resource names. The following table lists the APIs and the resource name they belong to.

### Table 35: EIM Event Categories. EIM Event Categories

<td></td>
</tr>
<tr>
<td>eimRemovePolicyFilter</td>
<td></td>
</tr>
<tr>
<td>eimRemoveRegistry</td>
<td></td>
</tr>
<tr>
<td>eimSetAttribute</td>
<td></td>
</tr>
</tbody>
</table>
### Table 35: EIM Event Categories. EIM Event Categories (continued)

<table>
<thead>
<tr>
<th>EIM API</th>
<th>Resource Name</th>
<th>EIM. domain name. CONNECT</th>
<th>EIM. domain name. ADMIN</th>
<th>EIM. domain name. LOOKUP</th>
<th>No logging performed</th>
</tr>
</thead>
<tbody>
<tr>
<td>eimSetConfigurationExt</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>X</td>
</tr>
</tbody>
</table>

### Note:
1. * Authentication failures are always logged for the EIM connect APIs.
2. ** Not found conditions are logged in addition to success and failure for the lookup APIs.
3. *** eimDestroyHandle events are only logged after a successful connect.

#### How events are audited

Events can be audited by one of the following methods:
- setting SETROPTS LOGOPTIONS
- enabling auditing for resources in the RAUDITX class
- enabling auditing for a specific user

There are a number of setup steps that must be performed by the security administrator before EIM events are logged. The user id of the EIM application must be given the authority to use the auditing service.

```system
RDEFINE FACILITY IRR.RAUDITX UACC(NONE)
PERMIT IRR.RAUDITX CLASS(FACILITY) ID(userid) ACCESS(READ)
SETR CLASSACT(FACILITY)
```

With this basic configuration, failures to connect to the EIM domain because of bind failures due to bad passwords are logged.

The security administrator or auditor can issue additional commands to control logging:

- Activate (or deactivate) logging for all EIM events involving all EIM domains by using SETROPTS LOGOPTIONS for the RAUDITX class. The RAUDITX class must be active for the SETROPTS LOGOPTIONS settings to take effect:

  ```system
  SETROPTS LOGOPTIONS(auditing-level(RAUDITX))
  ```

  where the auditing-level can be ALWAYS, NEVER, SUCCESSES, FAILURES, or DEFAULT.

- Activate or deactivate logging for a subset of EIM events by using SETROPTS LOGOPTIONS(DEFAULTS(RAUDITX)). The commands are:

  ```system
  SETROPTS LOGOPTIONS(DEFAULT(RAUDITX))
  RDEFINE RAUDITX profile-name UACC(NONE)
  PERMIT profile-name CLASS(RAUDITX) ID(user or group) ACCESS(READ)
  SETROPTS CLASSACT(RAUDITX)
  SETROPTS RACLIST(RAUDITX) or SETROPTS RACLIST(RAUDITX) REFRESH
  ```

- Activate or deactivate logging for a particular user:

  ```system
  ALTUSER user id UAUDIT
  ```

Generic profile names may be used when generics are activated for the RAUDITX class:

```system
SETR GENERIC(RAUDITX)
```
This is one approach for activating logging of EIM events. Consult with your security administrator for other options. See \textit{z/OS Security Server RACF Command Language Reference} and \textit{z/OS Security Server RACF Security Administrator’s Guide} for more information on the RACF commands, general resources, RACLST processing, and generic profile processing.

\textbf{SETROPTS LOGOPTIONS} activates or deactivates event logging for all resources in a class. The auditor must have the RACF authority required by the \texttt{SETROPTS} command. See \textit{z/OS Security Server RACF Command Language Reference} for more details on the authorities required to issue commands.

Following are the combinations of \texttt{SETROPTS} commands that can be used to enable or disable auditing for all EIM events in all EIM domains:

\begin{table}[h]
\begin{tabular}{|l|l|l|}
\hline
\textbf{Command} & \textbf{Results} & \textbf{Explanation} \\
\hline
\texttt{SETROPTS LOGOPTIONS(NEVER(RAUDITX))} & No log records except authentication connection failures & No log records are written for any domain except for connection failures. \\
\hline
\texttt{SETROPTS LOGOPTIONS(ALWAYS(RAUDITX))} & Successful or failure authorization or authentication & Log records are written for all EIM events in all domains. \\
\hline
\texttt{SETROPTS LOGOPTIONS(SUCCESES(RAUDITX))} & Successful and connection failure records & Success records are written for all EIM events in all domains. \textbf{Note:} This applies to all resources in the RAUDITX class. \\
\hline
\texttt{SETROPTS LOGOPTIONS(FAILURES(RAUDITX))} & Failure records & Failure records are written for all EIM events in all domains. \\
\hline
\texttt{SETROPTS LOGOPTIONS(DEFAULTS(RAUDITX))} & None. & The decision to log is determined by profiles in the RAUDITX class. \\
\hline
\end{tabular}
\end{table}

\textbf{Note:} When you enable auditing using \texttt{SETROPTS}, you are enabling auditing for all applications that use the RAUDITX class, not just EIM.

Auditing can also be enabled and controlled for a specific profile. In this case, the audit settings set by the profile owner or auditor are used to determine when and what to audit. Therefore, the profile owner has more direct control over auditing of their profiles.

\begin{table}[h]
\begin{tabular}{|l|l|l|}
\hline
\textbf{Commands} & \textbf{Results} & \textbf{Explanation} \\
\hline
\texttt{RDEFINE RAUDITX EIM.* AUDIT(...) or RALTER RAUDITX EIM.* GLOBALAUDIT(...)} & Success and/or failure & Log records are written for all EIM events for all users in all domains. \\
\hline
\texttt{RDEFINE RAUDITX EIM.*.CONNECT AUDIT(...) or RALTER RAUDITX EIM.*.CONNECT GLOBALAUDIT(...)} & Connect success and failure. Disconnect success. & Log records are written only for connect / disconnects for all users in all domains. \\
\hline
\end{tabular}
\end{table}
Generics must be active for the RAUDITX class before the profiles EIM.*, EIM.*.CONNECT, EIM.*.ADMIN, or EIM.*.LOOKUP are created. Use the SETROPTS GENERIC(RAUDITX) command to enable generics.

Additionally, an auditor can activate logging of events for a specific user by issuing the following:

```
ALTUSER userid UAUDIT
```

In this case, all events for this user are audited, including non-EIM events.

Regardless of the level at which auditing is enabled, the following events are always audited:

**EIM.domain name.CONNECT**

All connection authentication failures with an EIM domain controller

### What goes into an audit record

For each audited event, the following information is captured:

- information about the event:
  - general event code
  - the event code qualifier (success, bind failure, not found)
  - the name of the EIM API that logged the event (C/C++ API name)
- the EIM domain URL
- the user
  - the bind user name
  - the current RACF user ID
- the input parameters to the EIM API and in some cases additional information about the event, such as the UUID for the EIM identifier
- the results of the event in some cases such as the user IDs returned by an eimGetTargetFromSource
- the reasons the event was logged (EIM required logging of authentication failures, SETROPTS LOGOPTION settings, the audit settings on the RACF profile that covers the resource name representing the event)
- a link value which is used to identify multiple log records that were generated for a single event

### Working with audit records

The EIM events are logged in an SMF dataset as type 83 subtype 2 records. The log record is a mixture of binary and EBCDIC data. The general format of SMF Type 83 records is described in *z/OS Security Server RACF Macros and Interfaces*, in the chapter "SMF records", section "Record type 83: Security Events."
You can use the RACF SMF Unload utility to reformat the EIM SMF type 83 subtype 2 records for easier analysis. The audit records can be used to identify access violations or determine patterns of usage from your users. These audit records can be in the following different forms:

- A tabular format, suitable for import to a relational database manager.
- eXtensible Markup Language (XML) documents

Information on how to use the RACF SMF Unload utility can be found in z/OS Security Server RACF Auditor’s Guide. This book describes how the reformatted data can be further processed by Db2, DFSORT, and XML applications.

The next sections gives details on the different formats of the EIM event data:

- The layout of the EIM data contained in an SMF type 83 subtype 2 record
- The schema definition for the EIM XML elements
- Field names and column positions of the EIM data in the tabular output and sample Db2 statements for loading the EIM data into Db2

The SMF Record Type 83 subtype 2 records

When auditing is enabled for EIM events, SMF record type 83 subtype 2 records are recorded in the SMF dataset. Each logged EIM event has a unique event code with a corresponding event code qualifier, or value that indicates if the event succeeded, failed because the end user was not authorized, or if the requested data was not found. The event code and event code qualifiers are described in the following table.

<table>
<thead>
<tr>
<th>Event</th>
<th>Command / Service</th>
<th>Code Qualifier Dec (Hex)</th>
<th>Description</th>
<th>Relocate type sections (possible SMF83TP2 / SMF83DA2 values)</th>
</tr>

The XML output from the RACF SMF Unload Utility

The EIM XML elements generated by the RACF SMF Unload utility for an EIM event are described by the XML schema document IRREIMSC which can be found in SYS1.SAMPLIB.

The following is a copy of the EIM schema document.

```xml
<?xml version="1.0" encoding="ebcdic-cp-us" ?>
<xs:schema targetNamespace="http://www.ibm.com/xmlns/zOS/EIMSchema"
xmlns:xs="http://www.w3.org/2001/XMLSchema"
xmlns="http://www.ibm.com/xmlns/zOS/EIMSchema">
  <!-- PROPRIETARY STATEMENT -->
  <!-- LICENSED MATERIALS - PROPERTY OF IBM -->
  <!-- THIS MACRO IS "RESTRICTED MATERIALS OF IBM" -->
  <!-- 5637-A01 (C) COPYRIGHT IBM CORP. 2005 -->
  <!-- STATUS= HRF7720 -->
  <!-- END_OF_PROPRIETARY_STATEMENT -->

  <!-- 01* EXTERNAL CLASSIFICATION: OTHER -->
  <!-- 01* END OF EXTERNAL CLASSIFICATION: -->

  This SAMPLIB member is only an example. The value
  on each statement is not necessarily an IBM-recommended
  value. Installations may use this member to validate XML
  documents produced by the RACF SMF Data Unload Utility

  Name: HITSHEM

  Description: Define the EIM XML grammar used by the XML
  instance documents produced by the RACF SMF Data Unload Utility (IRRADU00).

  Operation: This is an XML schema document that defines the XML tag language used by the RACF SMF Data Unload Utility (IRRADU00) XML instance documents containing EIM events.

The tabular output from the RACF SMF Unload utility

A general description of the format of the tabular records created by the RACF SMF Unload Utility can be found in *z/OS Security Server RACF Macros and Interfaces*, in the chapter “The format of the unloaded SMF type 83 data”.

For EIM events, SMF Unload reserves two spaces between fields that appear after the header information. When the length of a value in the SMF type 83 subtype 2 record exceeds the available field length in the tabular output, SMF Unload will insert a “+” in the character position following indicating more data is available. This additional data can be viewed by reading the logged SMF record or by creating an XML document from the logged SMF record.

The following table describes the format of the header portion of the record. RACF constructs the header portion of the record from the SMF record. Because each of the SMF record types that SMF Unload processes contain different data, some fields of the header portion of the unloaded SMF record contain blanks. When working with the sample Db2 statements for loading the data into Db2, the `<col_id>` string is replaced by the column identifier for each field created. For EIM fields, the `<col_id>` may have the values:

<table>
<thead>
<tr>
<th><code>&lt;col_id&gt;</code></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EIMC</td>
<td>EIM connection events</td>
</tr>
<tr>
<td>EIML</td>
<td>EIM lookup events</td>
</tr>
</tbody>
</table>

Table 40: `<col_id>` values
Table 40: `<col_id>` values (continued)

<table>
<thead>
<tr>
<th><code>&lt;col_id&gt;</code></th>
<th>Description</th>

</tbody>
</table>

The data following the header in the tabular record varies according to the EIM event that was recorded. There are four EIM event types:

<table>
<thead>
<tr>
<th>Event Code from SMF type 83 subtype 2 records</th>
<th>Tabular output Event Type strings</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>*CONNECT</td>
</tr>
<tr>
<td>2</td>
<td>*LOOKUP</td>
</tr>
<tr>
<td>3</td>
<td>*ADMIN1</td>
</tr>
<tr>
<td>4</td>
<td>*ADMIN2</td>
</tr>
</tbody>
</table>
The following tables describe the data that may appear in the tabular record for each of the EIM event types and the event qualifiers for each event type.

### Table 42: Event-specific fields for EIM connection events (EIMC_EVENT_TYPE is "*CONNECT"). Event-specific fields for EIM connection events (EIMC_EVENT_TYPE is "*CONNECT")

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Type</th>
<th>Length</th>
<th>Start Position</th>
<th>End Position</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>EIMC_API</td>
<td>Char</td>
<td>128</td>
<td>3000</td>
<td>3127</td>
<td>EIM API Name</td>
</tr>
<tr>
<td>EIMC_DOMAIN_URL</td>
<td>Char</td>
<td>128</td>
<td>3130</td>
<td>3257</td>
<td>Domain URL</td>
</tr>
<tr>
<td>EIMC_CONNECT_TYPE</td>
<td>Char</td>
<td>32</td>
<td>3260</td>
<td>3291</td>
<td>Connection type - SIMPLE, SIMPLE AND CRAM-MD5, SIMPLE CRAM_MD5 OPTIONAL, KERBEROS, SSL CLIENT AUTH</td>
</tr>
<tr>
<td>EIMC_BIND_USER</td>
<td>Char</td>
<td>512</td>
<td>3294</td>
<td>3805</td>
<td>Bind user</td>
</tr>
<tr>
<td>EIMC_CERT_LABEL</td>
<td>Char</td>
<td>128</td>
<td>3808</td>
<td>3935</td>

</tr>
<tr>
<td>EIMC_KEY_RING</td>
<td>Char</td>
<td>128</td>
<td>3938</td>
<td>4065</td>
<td>Key Ring</td>
</tr>
</tbody>
</table>

The event qualifiers (EIMC_EVENT_QUAL) for EIM connection events indicate whether or not the attempt to connect to an EIM domain succeeded or failed due to security events (for example a bad password was specified). The possible values are:

<table>
<thead>
<tr>
<th>Event qualifier (EIMC_EVENT_QUAL field in the tabular record)</th>
<th>Event qualifier value in the SMF Type 83 subtype 2 record</th>
<th>Event description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUCCESS</td>
<td>00</td>
<td>Successful connect to the domain controller or a disconnection from the domain controller</td>
</tr>
<tr>
<td>BINDFAIL</td>
<td>03</td>
<td>Unauthorized to connect to the domain controller</td>
</tr>
</tbody>
</table>

### Table 43: Event-specific fields for EIM lookup events (EIML_EVENT_TYPE is "*LOOKUP"). Event-specific fields for EIM lookup events (EIML_EVENT_TYPE is "*LOOKUP")

<tr>
<td>EIML_REG_USER_NAME</td>
<td>Char</td>
<td>64</td>
<td>5626</td>
<td>5689</td>
<td>Registry user name</td>
</tr>
</tbody>
</table>

The event qualifiers (EIML_EVENT_QUAL) for EIM lookup events indicate whether or not the attempt to retrieve a user ID mapping was found, not found, or failed due to security reasons (the bind distinguished name does not have authority to retrieve the user ID mapping). The possible EIM lookup qualifier values are:

<table>
<thead>
<tr>
<th>Event qualifier (EIML_EVENT_QUAL field in the tabular record)</th>
<th>Event qualifier value in the SMF Type 83 subtype 2 record</th>
<th>Event description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUCCESS</td>

<td>01</td>
<td>Insufficient authority to modify the EIM domain or retrieve information from the domain</td>
</tr>
</tbody>
</table>

Included in z/OS are sample Db2 statements that can be used to load the EIM tabular output into Db2 for further analysis.

The sample Db2 statements for defining the table space and tables used to contain the EIM data is in SYS1.SAMPLIB(ITYSDBTB).

The sample Db2 load utility statements are in SYS1.SAMPLIB(ITYSDBLD). They can be used to load the EIM tabular output records of SMF unload into tables created by ITYSDBTB.
Chapter 11. EIM APIs

[Programming Interface Information] The EIM APIs are a programming Interface. They are intended for customers to use in customer-written programs. [End Programming Interface Information]

This chapter provides information about EIM APIs, which are in alphabetical order. Before the APIs themselves, preliminary sections identify the authority to use the APIs and describe the EIM return code parameter, EimRC.

This chapter discusses C/C++ as well as Java APIs.

Authority to use APIs

To use most of the APIs, you must meet one of the following:

• Be an LDAP administrator
• Belong to an EIM-defined LDAP access control group

Different access groups can update or view different portions of the EIM domain and, therefore, have the authority to use different APIs.

Some APIs require additional authority granted through RACF profiles.

For information on access authorities, refer to “EIM access control” on page 26. The following APIs do not require the user to have an EIM authority:

• eimSetConfiguration
• eimRetrieveConfiguration
• eimCreateHandle
• eimDestroyHandle
• eimSetAttribute
• eimGetAttribute
• eimConnect
• eimConnectToMaster

Java APIs

Java APIs make EIM available to z/OS applications and servers written in Java. If your location uses programs written in Java and you wish to incorporate these EIM into these programs, you'll be able to use the Java EIM APIs to interface with EIM. Some benefits of this include:

• The ability to write EIM administrative and lookup applications in Java
• z/OS qualities of service in the Java-enabled APIs, specifically:
  1. Auditors can begin to track work requests as they are processed by their &eserver_logo; systems. Activity by the user IDs on different platforms may be traced back to the enterprise identifier
  2. Applications can use RACF profiles to store bind credentials (bind DNs and passwords) instead of less secure practices such as hard coding the values in their programs, defining side files to store the information, or creating yet another application unique mechanism for managing bind credentials
  3. Applications can use RACF profiles to store the registry names instead of hard coding them in the programs, or store them in configuration files with application unique tools for managing the information. RACF allows the stored registry names to be shared among all applications on the system.
• Support Kerberos and CRAM-MD5 authentication mechanisms through the JNI provider
• Use existing system identities and the new distributed technologies interchangeably
• Administrators will have a central repository for saving relationships between enterprise identifiers and user IDs. As EIM based administration applications become available and operating systems exploit EIM, creation and deletion of user IDs can be tied to identifiers in an EIM domain
• The combination of EIM and LDAP eliminates the need for creating new user identities and the software to manage them. EIM and LDAP can replace the need for costly infrastructure to distribute identities to different platforms
• The ability to transform identities to local representations across operating systems and use existing system authorization mechanisms to validate access to system resources.

Authorization to use EIM Services

Authorization details are included in the documentation for the Java APIs, including those methods that have special authorization requirements. This documentation is separate from the z/OS library. For more details see “Obtaining documentation for the Java APIs” on page 165.

Mapping C++ to Java APIs

The following table shows the Java equivalent to the EIM C/C++ API. Several calls to java methods may be required to obtain the same information as a single C/C++ API. In addition, some of the Java methods are used in several places. Use the table to help guide you with answers to any questions you may have about RACF authorization requirements or what information will be audited for the Java APIs.

**Obtaining documentation for the Java APIs**

The classes and methods for the EIM Java APIs are described in html files known as Javadoc. The Javadoc is the primary source of documentation for the application programmer using the EIM Java APIs. Javadoc is generated as html using the Javadoc tool. Since a browser is needed to view the Javadoc, the Javadoc must either be downloaded to the user’s workstation or viewed directly from an IBM public web site.

The Javadoc for the EIM Java APIs is available in eimzOS_DOC.jar. Javadoc is in html format and in ASCII encoding. The jar file can be downloaded to the workstation using ftp or other file transfer tool and then unjared for viewing locally.

To access the Javadoc files, do the following:

1. Extract the files from the eimzOS_DOC.jar using the jar utility
2. Open the file overview-summary.html using your browser. This file gives an overview of the APIs and contains hyperlinks to descriptions of the interfaces, classes, and methods.
3. Follow the HELP hyperlink or open the file help-doc.html to a general description of how Javadoc is organized.
EimRC -- EIM return code parameter for C/C++

All EIM APIs return an errno. If the EimRC parameter is not NULL, this EIM return code structure contains additional information about the error that was returned. You can use this to get a text description of the error.

The layout for EimRC follows:

```c
typedef struct EimRC {
    unsigned int memoryProvidedByCaller;        /* Input: Size of the entire RC structure. This is filled in by the caller. This is used to tell the API how much space was provided for substitution text */
    unsigned int memoryRequiredToReturnData; /* Output: Filled in by API to tell caller how much data could have been returned. Caller can then determine if the caller provided enough space (i.e. if the entire substitution string was able to be copied to this structure). */
    int returnCode;                            /* Same as the errno returned as the rc for the API */
    int messageCatalogSetNbr;                  /* Message catalog set number */
    int messageCatalogMessageID;               /* Message catalog message id */
    int ldapError;                             /* ldap error, if available */
    int sslError;                              /* ssl error, if available */
    char reserved[16];                         /* Reserved for future use */
    unsigned int substitutionTextLength;       /* Length of substitution text excluding a null-terminator which may or may not be present */
    char substitutionText[1];                  /* Further info describing the error. */
} EimRC;
```

Field descriptions

**memoryProvidedByCaller**

(Input)

The number of bytes the calling application provides for the error code. The number of bytes provided must be at least 48.

**memoryRequiredToReturnData**

(Output)

The length of the error informational message, in bytes, that is necessary for the API to return. If this is 0, no error was detected and none of the fields that follow this field in the structure are changed.

**returnCode**

(Output)

The errno returned for this API. This is the same as the return value for each API.

**messageCatalogSetNbr**

(Output)

The message set number for the EIM catalog. You can use this with the messageCatalogID to get the error message text.

**messageCatalogMessageID**

(Output)

The message ID number for the EIM catalog. You can use this with the messageCatalogSetNbr to get the error message text.

**ldapError**

(Output)

**sslError**

(Output)
An error code returned by an LDAP client API. The interpretation of the error code is in the substitution text.

**sslError**  
(Output)  
An error code returned by an LDAP client API. If not zero, this value will be displayed in the substitution text as the SSL reason code. Refer to the ldapssl.h header file in the LDAP Client API document for further information.

**reserved**  
(Output)  
Reserved for future use.

**substitutionTextLength**  
(Output)  
This field is set if any substitution text is returned. If there is no substitution text, this field is zero.

**substitutionText**  
(Output)  
Message substitution text.

---

### eimAddAccess

#### Purpose

Adds the user to an EIM access group identified by the access type.

#### Format

```c
#include <eim.h>

int eimAddAccess(EimHandle eim, EimAccessUser *accessUser, enum EimAccessType accessType, char *registryName, EimRC *eimrc)
```

#### Parameters

- **eim**  
  (Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

- **accessUser**  
  (Input) A structure that contains the name of the user requiring access. The user name can be:

  - A distinguished name
  - A Kerberos Principal

- **EIM_ACCESS_DN**  
  Indicates a distinguished name defined in an LDAP directory that you can use to bind to the EIM domain.

- **EIM_ACCESS_LOCAL_USER**  
  (z/OS does not support this. Use EIM_ACCESS_DN instead.) It indicates a local user name on the system where the API runs. The local user name is converted to the appropriate access ID for this system.
**EIM_ACCESS_KERBEROS**

Indicates a Kerberos identity, which is converted to the appropriate access ID. For example, `petejones@therealm` is converted to `ibm-kn=petejones@threalm`.

The EimAccessUser structure layout follows:

```c
enum EimAccessUserType {
    EIM_ACCESS_DN,
    EIM_ACCESS_KERBEROS,
    EIM_ACCESS_LOCAL_USER
};

typedef struct EimAccessUser {
    union {
        char *dn;
        char *kerberosPrincipal;
        char *localUser;
    } user;
    enum EimAccessUserType userType;
} EimAccessUser;
```

**accessType**

(Input) The type of access to add. Valid values are:

- **EIM_ACCESS_ADMIN** (0)
  Administrative authority to the entire EIM domain.

- **EIM_ACCESS_REG_ADMIN** (1)
  Administrative authority to all registries in the EIM domain.

- **EIM_ACCESS_REGISTRY** (2)
  Administrative authority to the registry specified in the registryName parameter.

- **EIM_ACCESS_IDENTIFIER_ADMIN** (3)
  Administrative authority to all of the identifiers in the EIM domain.

- **EIM_ACCESS_MAPPING_LOOKUP** (4)
  Authority to perform mapping lookup operations.

**registryName**

(Input) The name of the registry for which to add access. Registry names are case-independent (meaning not case-sensitive). This parameter is used only if accessType is EIM_ACCESS_REGISTRY. If accessType is anything other than EIM_ACCESS_REGISTRY, this parameter must be NULL.

The following special characters are not allowed in registry names:

```
, = + < > # ; \ *
```

**eimrc**

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

See the following:

- “eimListAccess” on page 271
- “eimListUserAccess” on page 321
- “eimQueryAccess” on page 326
- “eimRemoveAccess” on page 330

**Authorization**

**EIM data**

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:
• EIM administrator

**z/OS authorization**
No special authorization is needed.

### Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the `messageCatalogMessageID` field in the `eimrc` parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_ACCESS (1)</strong></td>
</tr>
<tr>
<td></td>
<td>Insufficient access to EIM data.</td>
</tr>
<tr>
<td>EBADDATA</td>
<td><code>eimrc</code> is not valid.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>Unable to allocate internal system object.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_NOLOCK (26)</strong></td>
</tr>
<tr>
<td></td>
<td>(z/OS does not return this value.) Unable to allocate internal system object.</td>
</tr>
<tr>
<td>ECONVERT</td>
<td>Data conversion error.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_DATA_CONVERSION (13)</strong></td>
</tr>
<tr>
<td></td>
<td>(z/OS does not return this value.) Error occurred when converting data between code pages.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Input parameter was not valid.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_ACCESS_TYPE_INVAL (2)</strong></td>
</tr>
<tr>
<td></td>
<td>Access type is not valid.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_ACCESS_USERTYPE_INVAL (3)</strong></td>
</tr>
<tr>
<td></td>
<td>Access user type is not valid.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_HANDLE_INVAL (17)</strong></td>
</tr>
<tr>
<td></td>
<td>EimHandle is not valid.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_PARM_REQ (34)</strong></td>
</tr>
<tr>
<td></td>
<td>Missing required parameter. Please check the API documentation.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_PTR_INVAL (35)</strong></td>
</tr>
<tr>
<td></td>
<td>(z/OS does not return this value.) Pointer parameter is not valid.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_REG_MUST_BE_NULL (55)</strong></td>
</tr>
<tr>
<td></td>
<td>Registry name must be NULL when access type is not EIM_ACCESS_REGISTRY.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Unable to allocate required space.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_NOMEM (27)</strong></td>
</tr>
<tr>
<td></td>
<td>No memory available. Unable to allocate required space.</td>
</tr>
<tr>
<td>ENOTCONN</td>
<td>LDAP connection has not been made.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_NOT_CONN (31)</strong></td>
</tr>
<tr>
<td></td>
<td>Not connected to LDAP. Use either the <code>eimConnect</code> or <code>eimConnectToMaster</code> API and try the request again.</td>
</tr>
</tbody>
</table>
**Return Value** | **Meaning**
---|---
EROFS | LDAP connection is for read-only. Need to connect to master.

**EIMERR_READ_ONLY (36)**
This LDAP connection has “read-only” access. A connection to the master LDAP server with read/write is required to complete the operation. Use the eimConnectToMaster API to get a write connection.

UNKNOWN | Unexpected exception.

**EIMERR_LDAP_ERR (23)**
Unexpected LDAP error. %s

**EIMERR_UNKNOWN (44)**
Unknown error or unknown system state.

### Example
The following illustrates adding the distinguished name of a user to the EIM Administrator access group.

```c
#include <eim.h>

int rc;
char eimerr[200];
EimRC * err;
EimHandle handle;
EimAccessUser user;

/* Set up error structure.                 */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Set up access user information          */
user.userType = EIM_ACCESS_DN;
user.user.dn="cn=pete,o=ibm,c=us";

/* Add access for this user.               */
rc = eimAddAccess(&handle,
    &user,
    EIM_ACCESS_ADMIN,
    NULL,
    err);
```

### eimAddApplicationRegistry

**Purpose**
Adds an application registry to the EIM domain. An application registry contains a subset of a system registry's user IDs.

**Format**

```c
#include <eim.h>

int eimAddApplicationRegistry(EimHandle *eim,
    char *registryName,
    char *eimerr,
    EimAccessUser error,
    EimAccessUser user);
```
Parameters

eim
(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

registryName
(Input) The name for this application registry. This name cannot have a NULL value and must be unique within the EIM domain. The uniqueness of the registry name is for the domain and not for the system registry that the application registry belongs to. Registry names are case-independent (meaning, not case-sensitive).

The following special characters are not allowed in registry names.

\, = + < > # ; \ *

registryType
(Input) A string form of an OID that represents the registry type and a user name normalization method. The normalization method is necessary because some registries are case-independent while others are case-dependent. EIM uses this information to make sure the appropriate search occurs. When a registry is case-independent, registry user names are converted to uppercase. See Chapter 12, “EIM header file and example,” on page 367 for more information. Users can define their own registry types. See “EIM registry definition” on page 11 for details.

The following are possible registry types:

- EIM_REGTYPE_RACF
- EIM_REGTYPE_OS400
- EIM_REGTYPE_KERBEROS_EX
- EIM_REGTYPE_KERBEROS_IG
- EIM_REGTYPE_WIN_DOMAIN_KERB_IG
- EIM_REGTYPE_AIX
- EIM_REGTYPE_NDS
- EIM_REGTYPE_LDAP
- EIM_REGTYPE_POLICY_DIRECTOR
- EIM_REGTYPE_TIVOLI_ACCESS_MANAGER
- EIM_REGTYPE_WIN2K
- EIM_REGTYPE_WINDOWS_LOCAL_WS
- EIM_REGTYPE_X509
- EIM_REGTYPE_LINUX
- EIM_REGTYPE_DOMINO_LONG
- EIM_REGTYPE_DOMINO_SHORT

description
(Input) The description for this new application registry. This parameter can be NULL.

systemRegistryName
(Input) The name of the system registry of which this application registry is a subset. This parameter cannot be NULL.

The following special characters are not allowed in registry names.

\, = + < > # ; \ *

**eimrc**

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

See the following:

- “eimAddSystemRegistry” on page 188
- “eimChangeRegistry” on page 200
- “eimListRegistries” on page 297
- “eimRemoveRegistry” on page 346

**Authorization**

**EIM data**

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator

**z/OS authorization**

No special authorization is needed.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>

</tbody>
</table>

**Example**

The following example illustrates creating a new EIM application registry:

```c
#include <eim.h>

int           rc;
char          eimerr[200];
EimRC       * err;
EimHandle     handle;

/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Add new application registry */
rc = eimAddApplicationRegistry(&handle,
                                "MyAppRegistry",
                                "MyAppRegistry", 200);
```
eimAddAssociation

**Purpose**

Associates a local identity in a specified user registry with an EIM identifier. EIM supports three kinds of associations:

- **Source**
- **Target**
- **Administrative**

(See “EIM associations” on page 15 for more information about these kinds of associations.)

All EIM associations are between an EIM identifier and a local user identity. An association is never directly between local user identities. For an EIM identifier to be useful in mapping lookup operations, it must have at least one "source" or at least one "target" association.

Associated source identities are user identities that are primarily for authentication purposes. You can use an associated source identity as the source identity of a mapping lookup operation (that is, with eimGetTargetFromSource), but you cannot find an associated source identity by making it the target of a mapping lookup operation.

Associated target identities are user identities that are primarily used to secure existing data. You can find an associated target identity as the result of a mapping lookup operation, but you cannot use an associated target identity as the source identity for a mapping lookup operation.

Administrative associations are used to show that an identity is associated with an EIM identifier. You cannot use an administrative association as the source or target of a mapping lookup operation.

You can use a single user identity as both a target and a source. You do this by creating both a source and a target association for the local user identity with the appropriate EIM identifier. Although this API supports an association type of EIM_SOURCE_AND_TARGET, it actually creates two associations.

**Format**

```c
#include <eim.h>

int eimAddAssociation(EimHandle               *eim,
                       enum EimAssociationType associationType,
                       EimIdentifierInfo       *idName,
                       char                    *registryName,
                       char                    *registryUserName,
                       EimRC                   *eimrc)
```

**Parameters**

- **eim**  
  (Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

- **associationType**  
  (Input) The type of association to add. Valid values are:

  - **EIM_TARGET (1)**  
    Add a target association.
**EIM_SOURCE (2)**
Add a source association.

**EIM_SOURCE_AND_TARGET (3)**
Add both a source association and a target association.

**EIM_ADMIN (4)**
Add an administrative association.

**idName**
(Input) A structure that contains the identifier name for this association. The layout of the EimIdentifierInfo structure follows:

```c
enum EimIdType {
    EIM_UNIQUE_NAME,
    EIM_ENTRY_UUID,
    EIM_NAME
};

typedef struct EimIdentifierInfo
{
    union {
        char       * uniqueName;
        char       * entryUUID;
        char       * name;
    } id;
    enum EimIdType        idtype;
} EimIdentifierInfo;
```

**idtype**
The idtype in the EimIdentifierInfo structure indicates which identifier name has been provided. EIM_UNIQUE_NAME finds at most one matching identifier. EIM_NAME results in an error if your EIM domain has more than one identifier containing the same name.

**registryName**
(Input) The registry name for the association. Registry names are case-independent (meaning, not case-sensitive).

The following special characters are not allowed in registry names:

```
, = + < > # ; \ *
```

**registryUserName**
(Input) The registry user name for the association. The API normalizes the registry user name according to the normalization method for the defined registry. The registry user name should begin with a non-blank character.

**eimrc**
(Input/Output) The structure in which to return error code information. If the return value is not 0, eimrc is set with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**
See the following:

- “eimGetAssociatedIdentifiers” on page 243
- “eimListAssociations” on page 275
- “eimRemoveAssociation” on page 333

**Authorization**
**EIM data**
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The authority that the access group has to the EIM data depends on the type of association being added.
For administrative and source associations, the access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM identifiers administrator

For target associations, the access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM registries administrator
- EIM registry X administrator

**z/OS authorization**

No special authorization is needed.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the `messageCatalogMessageID` field in the `eimrc` parameter for that value.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Example**

The following example illustrates adding an administrative, source, and target association for the same identifier:

```c
#include <eim.h>

int           rc;
char          eimerr[200];
EimRC       * err;
EimHandle     handle;
EimIdentifierInfo x;
```
eimAddIdentifier

Purpose
Creates an identifier in EIM related to a specific person or entity within an enterprise. This identifier is used to manage information and identify relationships for a specific user or identity.

Format

```c
#include <eim.h>

int eimAddIdentifier (EimHandle *eim, char *name, enum EimIdAction nameInUseAction, unsigned int *sizeOfUniqueName, char *uniqueName, char *description, EimRC *eimrc);
```

Parameters

- **eim**
  (Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

- **name**
  (Input) A name to use for this identifier.
The following characters are special characters that are not allowed in the identifier name.

\, \, = \, + \, < \, > \, \# \, ; \, \*  

**nameInUseAction**
(Input) The name for the new identifier must be unique. This value indicates the action to take if the provided name is already in use. Possible values are:

- **EIM_FAIL (0)**
  Do not generate a unique name; return an error.
- **EIM_GEN_UNIQUE (1)**
  Generate a unique name.

**sizeOfUniqueName**
(Input/Output) The size of the field in which to return the unique name. EIM ignores this parameter if **nameInUseAction** is **EIM_FAIL**. At input this parameter is the size the caller provides. On output it contains the actual size returned. This value should be the size of the name parameter plus an additional 20 bytes.

**uniqueName**
(Output) The space in which to return the unique identifier for this new EIM identifier. EIM ignores this parameter if **nameInUseAction** is **EIM_FAIL**.

**description**
(Input) Description for the new EIM identifier. This parameter can be NULL.

**eimrc**
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets **eimrc** with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

See the following:
- “**eimChangeIdentifier**” on page 196
- “**eimGetAssociatedIdentifiers**” on page 243
- “**eimListIdentifiers**” on page 287
- “**eimRemoveIdentifier**” on page 337

**Authorization**

**EIM data**
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM identifiers administrator

**z/OS authorization**
No special authorization is needed.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the **messageCatalogMessageID** field in the **eimrc** parameter for that value.

<td>Unexpected LDAP error.</td>
</tr>
<tr>
<td>EIMERR_UNKNOWN (44)</td>
<td>Unknown error or unknown system state.</td>
</tr>
</tbody>
</table>

**Example**

The following example illustrates adding an EIM identifier:

```c
#include <eim.h>

int           rc;
char          eimerr[200];
EimRC       * err;
EimHandle     handle;
char          unique[30];
unsigned int  sizeOfUnique = 30;

/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;
.
.
.
/* Add new identifier of Mary Smith */
rc = eimAddIdentifier(&handle,
   "Mary Smith",
   EIM_GEN_UNIQUE,
   &sizeOfUnique,
   unique,
   "The coolest person",
   err);
.
.
```

eimAddPolicyAssociation

**Purpose**

Add a policy mapping to a domain. Policy associations specify the target association for a mapping lookup operation without having to define specific source associations for all users. The three types of policies allowed are certificate, default registry, and default domain.

**Format**

```c
#include <eim.h>
int eimAddPolicyAssociation(EimHandle * eim,
    EimPolicyAssociationInfo * policyAssoc,
    EimRC * eimrc)
```

**Parameters**

**eim**

(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.
**policyAssoc**

(Input) The information about the policy association to be added. Valid types are:

**EIM_CERT_FILTER_POLICY**

Used to map user (or client) certificates with similar attributes to the same target identity in the target registry.

**EIM_DEFAULT_REG_POLICY**

Used to map any user in the specified source registry to the same target identity in the target registry.

**EIM_DEFAULT_DOMAIN_POLICY**

Used to map all users to the same target identity in the target registry.

The structure layout is as follows:

```c
enum EimAssociationType {
    EIM_ALL_ASSOC,            /* Not supported on this interface*/
    EIM_TARGET,               /* Not supported on this interface*/
    EIM_SOURCE,               /* Not supported on this interface*/
    EIM_SOURCE_AND_TARGET,    /* Not supported on this interface*/
    EIM_ADMIN,                /* Not supported on this interface*/
    EIM_CERT_FILTER_POLICY,   /* Policy is a certificate
                               filter policy association. */
    EIM_DEFAULT_REG_POLICY,   /* Policy is a default
                               registry policy association */
    EIM_DEFAULT_DOMAIN_POLICY /* Policy is a default policy for
                               the domain. */
};

typedef struct EimCertificateFilterPolicyAssociation
{
    char  * sourceRegistry; /* The source registry to add the
                             policy association to. */
    char  * filterValue;   /* The filter value of the policy. */
    char  * targetRegistry; /* The name of the target registry
                              that the filter value should
                              map to. */
    char  * targetRegistryUserName; /* The name of the target registry
                                      user name that the filter value
                                      should map to. */
} EimCertificateFilterPolicyAssociation;

typedef struct EimDefaultRegistryPolicyAssociation
{
    char  * sourceRegistry; /* The source registry to add the
                            policy association to. */
    char  * targetRegistry; /* The name of the target registry
                             that the policy should map to. */
    char  * targetRegistryUserName; /* The name of the target registry
                                       user name that the policy
                                       should map to. */
} EimDefaultRegistryPolicyAssociation;

typedef struct EimDefaultDomainPolicyAssociation
{
    char  * targetRegistry; /* The name of the target registry
                             that the policy should map to. */
    char  * targetRegistryUserName; /* The name of the target registry
                                       user name that the policy
                                       should map to. */
} EimDefaultDomainPolicyAssociation;

typedef struct EimPolicyAssociationInfo
{
    enum EimAssociationType type;
    union {
        EimCertificateFilterPolicyAssociation certFilter;
        EimDefaultRegistryPolicyAssociation defaultRegistry;
        EimDefaultDomainPolicyAssociation defaultDomain;
    } policyAssociation;
} EimPolicyAssociationInfo;
```

**eimrc**

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Authorization

EIM data

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM Registries Administrator
- EIM authority to an individual registry. This authority is needed to the target registry.

</tbody>
</table>

Example

The following example adds a default registry policy association.

```c
#include <eim.h>
#include <string.h>
.
.
int                      rc;
char                     eimerr[250];
EimRC                  * err;
EimHandle                handle;
EimPolicyAssociationInfo assocInfo;
.
/* Set up error structure. */
memset(eimerr,0x00,250);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 250;
.
.
```
eimAddPolicyFilter

Purpose

Adds a policy filter to the domain. A policy association can then be added to the filter value using the eimAddPolicyAssociation API.

Format

```c
#include <eim.h>

int eimAddPolicyFilter(EimHandle * eim, EimPolicyFilterInfo * filterInfo, EimRC * eimrc)
```

Parameters

**eim**

(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

**filterInfo**

(Info) The information about the policy filter to be added. Valid types are:

**EIM_CERTIFICATE_FILTER (1)**

Identifies that all certificates issued by the same Certificate Authority (CA) are mapped to the same target identity in the target registry. Or, all certificates from the same organization are mapped to the same target identity in the target registry.

The structure layout is as follows:

```c
enum EimPolicyFilterType {
    EIM_ALL_FILTERS,                  /* All policy filters -- not supported for this interface. */
    EIM_CERTIFICATE_FILTER           /* Policy filter is a certificate filter. */
};
typedef struct EimCertificatePolicyFilter {
    char  * sourceRegistry;         /* The source registry to add the policy filter to. */
    char  * filterValue;            /* The policy filter value. */
} EimCertificatePolicyFilter;
typedef struct EimPolicyFilterInfo {
    enum EimPolicyFilterType type;
    union {
        EimCertificatePolicyFilter certFilter;
    } filter;
} EimPolicyFilterInfo;
```

**eimrc**

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.
Related Information

- “eimListPolicyFilters” on page 293
- “eimFormatPolicyFilter” on page 233
- “eimAddPolicyAssociation” on page 181
- “eimRemovePolicyAssociation” on page 340
- “eimListRegistryAssociations” on page 309

Authorization

EIM data

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator

Return Values

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>
</tr>
<tr>
<td>EIMERR_ACCESS (1)</td>
<td>Insufficient access to EIM data.</td>
</tr>
<tr>
<td>EBADDATA</td>
<td>eimrc is not valid.</td>
</tr>
<tr>
<td>EIMERR_NOREG (28)</td>
<td>EIM Registry not found or insufficient access to EIM data.</td>
</tr>
<tr>
<td>EBADNAME</td>
<td>Registry name is not valid, insufficient access to EIM data, or policy filter value is not found.</td>
</tr>
<tr>
<td>EIMERR_NOLOCK (26)</td>
<td>(z/OS does not return this value.) Unable to allocate internal system object.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>Unable to allocate internal system object.</td>
</tr>
<tr>
<td>ECONVERT</td>
<td>Data conversion error.</td>
</tr>
<tr>
<td>EIMERR_DATA_CONVERSION (13)</td>
<td>(z/OS does not return this value.) Error occurred when converting data between code pages.</td>
</tr>
</tbody>
</table>
### Return Value | Meaning
--- | ---
EINVAL | Input parameter was not valid.

**EIMERR_CHAR_INVALID (21)**
A restricted character was used in the object name. Check the API for a list of restricted characters.

**EIMERR_FUNCTION_NOT_SUPPORTED (70)**
The specified or configured EIM Domain controller does not support this API.

**EIMERR_HANDLE_INVALID (17)**
EimHandle is not valid.

**EIMERR_PARM_REQ (34)**
Missing required parameter. Check the API documentation.

**EIMERR_PTR_INVALID (35)**
(z/OS does not return this value.) Pointer parameter is not valid.

ENOMEM | Unable to allocate required space.

**EIMERR_NOMEM (27)**
No memory available. Unable to allocate required space.

ENOTCONN | LDAP connection has not been made.

**EIMERR_NOT_CONN (31)**
Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.

EROFS | The connection is for read-only. Need to connect to master.

**EIMERR_READ_ONLY (36)**
This connection has "read-only" access. A connection to the master LDAP server with read/write is required to complete this operation. Use eimConnectToMaster to get a write connection.

EUNKNOWN | Unexpected exception.

**EIMERR_LDAP_ERR (23)**
Unexpected LDAP error.

**EIMERR_UNKNOWN (44)**
Unknown error or unknown system state.

**EIMERR_UNEXP_OBJ_VIOLATION (56)**
Unexpected object violation.

### Example
```c
#include <eim.h>
#include <string.h>

int                 rc;
char                eimerr[250];
EimRC             * err;
EimHandle           handle;
EimPolicyFilterInfo filterInfo;

/* Set up error structure. */
memset(eimerr, 0x00, 250);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 250;

/* Set up policy filter information */
filterInfo.type = EIM_CERTIFICATE_FILTER;
```
filterInfo.filter.certFilter.sourceRegistry = "MySourceRegistry";
filterInfo.filter.certFilter.filterValue = "<IDN>OU=Certified User,O=A Certificate Authority,L=Internet</IDN>";

/* Add the policy filter */
rc = eimAddPolicyFilter(&handle,
                        &filterInfo,
                        err);

Purpose

Adds a system registry to the EIM domain. After you add it, this registry participates in the EIM domain. You can make mapping associations only with identities in registries that are currently participating in the EIM domain.

Format

```
#include <eim.h>

int eimAddSystemRegistry(EimHandle      *eim,
                         char           *registryName,
                         char           *registryType,
                         char           *description,
                         char           *URI,
                         EimRC          *eimrc)
```

Parameters

**eim**

(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

**registryName**

(Input) The name for this system registry. This name cannot have a NULL value and must be unique within the EIM domain. Registry names are case-independent (meaning, not case-sensitive).

The following special characters are not allowed in registry names.

```
, = + < > # ; \ *
```

**registryType**

(Input) A string form of an OID that represents the registry type and a user name normalization method. The normalization method is necessary because some registries are case-independent and others are case-dependent. EIM uses this information to make sure the appropriate search occurs. When a registry is case-independent, registry user names are converted to uppercase. The following are possible registry types:

- EIM_REGTYPE_RACF
- EIM_REGTYPE_OS400
- EIM_REGTYPE_KERBEROS_EX
- EIM_REGTYPE_KERBEROS_IG
- EIM_REGTYPE_WIN_DOMAIN_KERB_IG
- EIM_REGTYPE_AIX
- EIM_REGTYPE_NDS
• EIM_REGTYPE_LDAP
• EIM_REGTYPE_POLICY_DIRECTOR
• EIM_REGTYPE_TIVOLI_ACCESS_MANAGER
• EIM_REGTYPE_WIN2K
• EIM_REGTYPE_WINDOWS_LOCAL_WS
• EIM_REGTYPE_X509
• EIM_REGTYPE_LINUX
• EIM_REGTYPE_DOMINO_LONG
• EIM_REGTYPE_DOMINO_SHORT

description
(Input) The description for this new system registry entry. This parameter can be NULL.

URI
(Input) The LDAP URI (Universal Resource Identifier) for this registry, if available.

If the system registry is accessible through LDAP, then for documentation purposes you can set the URI as the URL for the system registry.

Example:
If the following three premises are true:
• The LDAP server is running on z/OS with the host name some.ldap.host
• The LDAP server is listening on port 389
• The LDAP server is configured with the RACF SDBM and has the suffix cn=RACFA,o=ibm,c=us

Then the URI could be set to the following:

```
ldap://some.ldap.host:389/profileType=User, cn=RACFA, o=ibm, c=us
```

eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information
See the following:
• “eimAddApplicationRegistry” on page 170
• “eimChangeRegistry” on page 200
• “eimListRegistries” on page 297
• “eimRemoveRegistry” on page 346

Authorization

EIM data
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:
• EIM administrator

z/OS authorization
No special authorization is needed.
### Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the `messageCatalogMessageID` field in the `eimrc` parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_ACCESS (1)</strong></td>
</tr>
<tr>
<td></td>
<td>Insufficient access to EIM data.</td>
</tr>
<tr>
<td>EBADDATA</td>
<td><code>eimrc</code> is not valid.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>Unable to allocate internal system object.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_NOLOCK (26)</strong></td>
</tr>
<tr>
<td></td>
<td>(z/OS does not return this value.) Unable to allocate internal system object.</td>
</tr>
<tr>
<td>ECONVERT</td>
<td>Data conversion error.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_DATA_CONVERSION (13)</strong></td>
</tr>
<tr>
<td></td>
<td>(z/OS does not return this value.) Error occurred when converting data between code pages.</td>
</tr>
<tr>
<td>EEXIST</td>
<td>EIM registry entry already exists.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_REGISTRY_EXISTS (37)</strong></td>
</tr>
<tr>
<td></td>
<td>The registry entry already exists within the particular domain.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Input parameter was not valid.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_CHAR_INVAL (21)</strong></td>
</tr>
<tr>
<td></td>
<td>A restricted character was used in the object name. Check the API for a list of restricted characters.</td>

<td><strong>EIMERR_HANDLE_INVAL (17)</strong></td>
</tr>
<tr>
<td></td>
<td>EimHandle is not valid.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_PARM_REQ (34)</strong></td>
</tr>
<tr>
<td></td>
<td>Missing required parameter. Check the API documentation.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_PTR_INVAL (35)</strong></td>
</tr>
<tr>
<td></td>
<td>(z/OS does not return this value.) Pointer parameter is not valid.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Unable to allocate required space.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_NOMEM (27)</strong></td>
</tr>
<tr>
<td></td>
<td>No memory available. Unable to allocate required space.</td>
</tr>
<tr>
<td>ENOTCONN</td>
<td>LDAP connection has not been made.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_NOT_CONN (31)</strong></td>
</tr>
<tr>
<td></td>
<td>Not connected to LDAP. Use either the <code>eimConnect</code> or <code>eimConnectToMaster</code> API and try the request again.</td>
</tr>
<tr>
<td>EROFS</td>
<td>The connection is for read-only. Need to connect to master.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_READ_ONLY (36)</strong></td>
</tr>
<tr>
<td></td>
<td>This connection has &quot;read-only&quot; access. A connection to the master LDAP server with read/write is required to complete this operation. Use <code>eimConnectToMaster</code> to get a write connection.</td>
</tr>
</tbody>
</table>
### Return Value

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>EUNDEFINED</td>
<td>Unexpected exception.</td>
</tr>
<tr>
<td>EIMERR_LDAP_ERR (23)</td>
<td>Unexpected LDAP error.</td>
</tr>
<tr>
<td>EIMERR_UNKNOWN (44)</td>
<td>Unknown error or unknown system state.</td>
</tr>
</tbody>
</table>

### Example

The following example illustrates creating a new EIM system registry:

```c
#include <eim.h>

int rc;
char eimerr[200];
EimRC * err;
EimHandle handle;

/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Add new system registry */
rc = eimAddSystemRegistry(&handle,
                          "MyRegistry",
                          EIM_REGTYPE_OS400,
                          "The first registry",
                          NULL, /* No URI specified for this registry */
                          err);
```

### eimChangeDomain

#### Purpose

Changes an attribute for the EIM domain entry.

#### Format

```c
#include <eim.h>

int eimChangeDomain(char * ldapURL,
                     EimConnectInfo * connectInfo,
                     enum EimDomainAttr * attrName,
                     char * attrValue,
                     enum EimChangeType * changeType,
                     EimRC * eimrc)
```
Parameters

ldapURL
(Input) A uniform resource locator (URL) that contains the EIM host information. This parameter is required. This URL has the following format:

ldap://host:port/dn

or

ldaps://host:port/dn

host:port
Name of the host on which the EIM domain controller is running. (The port number is optional. If not specified, the default LDAP or LDAPS port will be used.)

dn
Distinguished name of the domain to change.

Example:

ldap://eimsystem:389/ibm-eimDomainName=myEimDomain,o=mycompany,c=us
ldaps://eimsystem:636/ibm-eimDomainName=myEimDomain,o=ibm,c=us

Note: In contrast with ldap, ldaps indicates that this host and port combination uses SSL and TLS.

connectInfo
(Input) Connect information. This parameter provides the information required to bind to LDAP. If the system is configured to connect to a secure port, EimSSLInfo is required.

For the EIM_SIMPLE connect type, the creds field should contain the EimSimpleConnectInfo structure with a binddn and password.

EimPasswordProtect determines the level of password protection on the LDAP bind.

EIM_PROTECT_NO (0)
The clear-text password is sent on the bind.

EIM_PROTECT_CRAM_MD5 (1)
The protected password is sent on the bind. The server side must support cram-md5 protocol to send the protected password.

EIM_PROTECT_CRAM_MD5_OPTIONAL (2)
The protected password is sent on the bind if the cram-md5 protocol is supported. Otherwise, the clear-text password is sent.

For EIM_KERBEROS, the default logon credentials are used. The kerberos_creds field must be NULL.

For EIM_CLIENT_AUTHENTICATION, the creds field is ignored. The ssl field must point to a valid EimSSLInfo structure. The keyring field is required in the EimSSLInfo structure. It can be the name of a System SSL key database file or a RACF keyring name. The keyring_pw field is required when the keyring is the name of a System SSL key database file. The certificateLabel field is optional. If it is NULL the default certificate in the keyring is used.

The structure layouts follow:

```c
enum EimPasswordProtect {
    EIM_PROTECT_NO,
    EIM_PROTECT_CRAM_MD5,
    EIM_PROTECT_CRAM_MD5_OPTIONAL
};

enum EimConnectType {
    EIM_SIMPLE,
    EIM_KERBEROS,
    EIM_CLIENT_AUTHENTICATION
};
```
typedef struct EimSimpleConnectInfo
{
    enum EimPasswordProtect protect;
    char * bindDn;
    char * bindPw;
} EimSimpleConnectInfo;

typedef struct EimSSLInfo
{
    char * keyring;
    char * keyring_pw;
    char * certificateLabel;
} EimSSLInfo;

typedef struct EimConnectInfo
{
    enum EimConnectType type;
    union {
        gss_cred_id_t * kerberos;
        EimSimpleConnectInfo simpleCreds;
    } creds;
    EimSSLInfo * ssl;
} EimConnectInfo;

attrName
(Input) The attribute to be updated. Valid values are:

**EIM_DOMAIN_DESCRIPTION (0)**
Changes the description for the EIM domain. Valid changeType is EIM_CHG (0).

**EIM_DOMAIN_POLICY_ASSOCIATIONS (1)**
Change the indicator for whether or not the domain supports policy associations in a mapping lookup. By default, the policy associations are not enabled. Valid changeType is EIM_ENABLE (3) or EIM_DISABLE (4).

attrValue
(Input) The new value for the attribute. This value can be a NULL string (for example, """). If the attribute being changed is EIM_DOMAIN_POLICY_ASSOCIATIONS, this value must be NULL.

changeType
(Input) The type of change to make. This could be add, remove, or change, enable or disable. The attrName parameter indicates which type is allowed for each attribute. Valid values are:

**EIM_CHG (0)**
The attribute is set to the new value.

**EIM_ENABLE (3)**
Allow policy associations in a mapping lookup.

**EIM_DISABLE (4)**
Do not allow policy associations in a mapping lookup.

eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, eimrc is set with additional information. This parameter can be NULL. For the format of the structure, see "EimRC -- EIM return code parameter for C/C++" on page 166.

<tr>
<td>EIMERR_LDAP_ERR (23)</td>
<td>Unexpected LDAP error.</td>
</tr>
<tr>
<td>EIMERR_UNKNOWN (44)</td>
<td>Unknown error or unknown system state.</td>
</tr>
</tbody>
</table>
The following example changes the description of the specified EIM domain and enables the use of policy associations for the domain:

```c
#include <eim.h>
#include <stdio.h>
#include <string.h>

int main(int argc, char *argv[]) {
    int rc;
    char eimerr[200];
    EimRC * err;
    EimConnectInfo con;

    char * ldapURL = "ldap://eimsystem:389/ibm-eimDomainName=myEimDomain,o=mycompany,c=us";

    /* Set up connection information */
    con.type = EIM_SIMPLE;
    con.creds.simpleCreds.protect = EIM_PROTECT_NO;
    con.creds.simpleCreds.bindDn = "cn=admin";
    con.creds.simpleCreds.bindPw = "secret";
    con.ssl = NULL;

    /* Set up error structure. */
    memset(eimerr,0x00,200);
    err = (EimRC *)eimerr;
    err->memoryProvidedByCaller = 200;

    /* Change the description for this domain. */
    if (0 != (rc = eimChangeDomain(ldapURL,
            con,
            EIM_DOMAIN_DESCRIPTION,
            "This is the new description",
            EIM_CHG,
            err)))
        printf("Change domain description failed; return code = %d", rc);

    /* Set up connection information for second call */
    con.type = EIM_SIMPLE;
    con.creds.simpleCreds.protect = EIM_PROTECT_NO;
    con.creds.simpleCreds.bindDn = "cn=admin";
    con.creds.simpleCreds.bindPw = "secret";
    con.ssl = NULL;

    /* reset error structure. */
    memset(eimerr,0x00,200);
    err->memoryProvidedByCaller = 200;

    /* Enable Policy Associations for this domain. */
    if (0 != (rc = eimChangeDomain(ldapURL,
            con,
            EIM_DOMAIN_POLICY_ASSOCIATIONS,
            NULL,
            EIM_ENABLE,
            err)))
        printf("Enable policy associations failed; return code = %d", rc);

    return 0;
}
```

eimChangeIdentifier

**Purpose**

Modifies an existing EIM identifier.

**Format**

```c
#include <eim.h>
```
int eimChangeIdentifier(EimHandle *eim, EimIdentifierInfo *idName, enum EimIdentifierAttr attrName, char *attrValue, enum EimChangeType changeType, EimRC *eimrc)

Parameters

eim
(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

idName
(Input) A structure that contains the name for this identifier.

The following special characters are not allowed in identifier names.

, = + < > ; \ *

The layout of the EimIdentifierInfo structure follows:

```c
enum EimIdType {
    EIM_UNIQUE_NAME,
    EIM_ENTRY_UUID,
    EIM_NAME,
};

typedef struct EimIdentifierInfo {
    union {
        char       * uniqueName;
        char       * entryUUID;
        char       * name;
    } id;
    enum EimIdType        idtype;
} EimIdentifierInfo;
```

idtype
The idtype in the EimIdentifierInfo structure indicates which identifier name has been provided. EIM_UNIQUE_NAME finds at most one matching identifier. EIM_NAME results in an error if your EIM domain has more than one identifier containing the same name.

attrName
The attribute to be updated. Valid values are:

**EIM_IDENTIFIER_DESCRIPTION (0)**
Change the identifier description. Valid `changeType` is EIM_CHG (0).

**EIM_IDENTIFIER_NAME (1)**
Add or remove a name attribute for this identifier. Valid `changeType` can be:

- EIM_ADD (1)
- EIM_RMV (2)

**EIM_IDENTIFIER_ADDL_INFO (2)**
Add or remove an additional information attribute for this identifier. Additional information is user-defined data. Valid `changeType` can be:

- EIM_ADD (1)
- EIM_RMV (2)

attrValue
(Input) The new value for the attribute. This value can be a NULL string (for example, "").

changeType
(Input) The type of change to make. On z/OS, this can be one of the following:
**EIM_CHG (0)**
EIM sets the attribute to the new value. EIM creates the attribute if it does not already exist.

**EIM_ADD (1)**
EIM adds the attribute and its value to the identifier. EIM creates the attribute if it does not already exist.

**EIM_RMV (2)**
EIM removes `attrValue` from the attribute in the identifier entry. EIM removes the attribute itself from the entry if no values remain for the attribute. To remove the entire attribute, use NULL for `attrValue`.

The `attrName` parameter indicates the type allowed for each attribute.

**eimrc**
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets `eimrc` with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**
See the following:
- “eimAddIdentifier” on page 178
- “eimGetAssociatedIdentifiers” on page 243
- “eimListIdentifiers” on page 287
- “eimRemoveIdentifier” on page 337

**Authorization**

**EIM data**
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:
- EIM administrator
- EIM identifiers administrator

**z/OS authorization**
No special authorization is needed.

**Return Values**
The following table lists the return values from the API. Following each return value is the list of possible values for the `messageCatalogMessageID` field in the `eimrc` parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>

<td><strong>EIMERR_IDNAME_AMBIGUOUS (20)</strong></td>
</tr>
<tr>
<td></td>
<td>More than one EIM identifier was found that matches the requested Identifier name.</td>
</tr>
<tr>
<td></td>
<td><strong>EIMERR_NOIDENTIFIER (25)</strong></td>
</tr>
<tr>
<td></td>
<td>EIM identifier not found or insufficient access to EIM data.</td>
</tr>
</tbody>
</table>
### Return Value | Meaning
--- | ---
EBUSY | Unable to allocate internal system object.
| **EIMERR_NOLOCK** (26) | (z/OS does not return this value.) Unable to allocate internal system object.
ECONVERT | Data conversion error.
| **EIMERR_DATA_CONVERSION** (13) | (z/OS does not return this value.) Error occurred when converting data between code pages.
EINVAL | Input parameter was not valid.
| **EIMERR_ATTR_INVAL** (5) | Attribute name is not valid.
| **EIMERR_CHGTYPE_INVAL** (9) | This change type is not valid with the requested attribute. Please check the API documentation.
| **EIMERR_HANDLE_INVAL** (17) | EimHandle is not valid.
| **EIMERR_IDNAME_TYPE_INVAL** (52) | The EimIdType value is not valid.
| **EIMERR_PARM_REQ** (34) | Missing required parameter. Please check the API documentation.
| **EIMERR_PTR_INVAL** (35) | (z/OS does not return this value.) Pointer parameter is not valid.
ENOMEM | Unable to allocate required space.
| **EIMERR_NOMEM** (27) | No memory available. Unable to allocate required space.
ENOTCONN | LDAP connection has not been made.
| **EIMERR_NOT_CONN** (31) | Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.
EROFS | LDAP connection is for read-only. Need to connect to master.
| **EIMERR_READ_ONLY** (36) | This LDAP connection has “read-only” access. A connection to the master LDAP server with read/write is required to complete the operation. Use the eimConnectToMaster API to get a write connection.
EUNKNOWN | Unexpected exception.
| **EIMERR_LDAP_ERR** (23) | Unexpected LDAP error.
| **EIMERR_UNKNOWN** (44) | Unknown error or unknown system state.

#### Example
The following example illustrates changing an EIM identifier description:

```c
#include <eim.h>

int rc;
```
char          eimerr[200];
EimRC       * err;
EimHandle     handle;
EimIdentifierInfo idInfo;

/* Set up error structure.                 */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;
.
.
.
/* Set up identifier information           */
idInfo.idtype = EIM_UNIQUE_NAME;
idInfo.id.uniqueName = "Mary Smith";

/* Change the description of the identifier */
rc = eimChangeIdentifier(&handle,
   &idInfo,
   EIMIDENTIFIER_DESCRIPTION,
   "This is a new description",
   EIM_CHG,
   err);
.
.
.
---

**eimChangeRegistry**

**Purpose**

Changes the attribute of a registry participating in the EIM domain.

**Format**

```
#include <eim.h>

int eimChangeRegistry(EimHandle *eim,
   char *registryName,
   enum EimRegistryAttr attrName,
   char *attrValue,
   enum EimChangeType changeType,
   EimRC *eimrc)
```

**Parameters**

**eim**

(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

**registryName**

(Input) The name of the registry to change. Registry names are case-independent (meaning, not case-sensitive).

The following special characters are not allowed in registry names:

```
, = + < > # ; \ *
```

**attrName**

(Input) The attribute to update. Valid values are:

**EIM_REGISTRY_DESCRIPTION (0)**

Change the registry description. Valid changeType is EIM_CHG (0).

**EIM_REGISTRY_LABELEDURI (1)**

Change the URI for the system registry. Valid changeType is EIM_CHG (0).
EIM_REGISTRY_MAPPING_LOOKUP (2)
Change the indicator for whether or not the registry supports mapping lookup operations. By default, mapping lookup operations are supported. Valid changeType is EIM_ENABLE (3) or EIM_DISABLE (4).

EIM_REGISTRY_POLICY_ASSOCIATIONS (3)
Change the indicator for whether or not the registry supports policy associations in a mapping lookup. By default, the policy associations are not supported. Valid changeType is EIM_ENABLE (3) or EIM_DISABLE (4).

attrValue
(Input) The new value for the attribute. The value can be a NULL string (for example, """). Specifically, if the attribute being changed is EIM_REGISTRY_MAPPING_LOOKUP or EIM_REGISTRY_POLICY_ASSOCIATIONS, this value must be NULL.

changeType
(Input) The type of change to make. On z/OS, this could be:

- EIM_CHG (0)
  EIM sets the attribute to the new value (0).
- EIM_ENABLE (3)
  Enable the change specified by attrname.
- EIM_DISABLE (4)
  Disable the change specified by attrname.

The attrName parameter indicates which changeType is allowed for each attribute.

eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information
See the following:
- “eimAddApplicationRegistry” on page 170
- “eimAddSystemRegistry” on page 188
- “eimListRegistries” on page 297
- “eimRemoveRegistry” on page 346

Authorization
EIM data
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM registries administrator
- EIM registry X administrator

z/OS authorization
No special authorization is needed.

Return Values
The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.
<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>

<td>EimHandle is not valid.</td>
</tr>
<tr>
<td><strong>EIMERR_PARM_REQ (34)</strong></td>
<td>Missing required parameter. Please check the API documentation.</td>
</tr>
<tr>
<td><strong>EIMERR_PTR_INVAL (35)</strong></td>
<td>Pointer parameter is not valid.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Unable to allocate required space.</td>
</tr>
<tr>
<td><strong>EIMERR_NOMEM (27)</strong></td>
<td>No memory available. Unable to allocate required space.</td>
</tr>
<tr>
<td>ENOTCONN</td>
<td>LDAP connection has not been made.</td>
</tr>
<tr>
<td><strong>EIMERR_NOT_CONN (31)</strong></td>
<td>Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.</td>
</tr>
<tr>
<td>EROFS</td>
<td>LDAP connection is for read-only. Need to connect to master. Use eimConnectToMaster to get a write connection or use the URL for the master EIM domain controller which is writeable.</td>
</tr>
<tr>
<td><strong>EIMERR_READ_ONLY (36)</strong></td>
<td>This LDAP connection has &quot;read-only&quot; access. A connection to the master LDAP server with read/write is required to complete this operation. Use eimConnectToMaster to get a write connection.</td>
</tr>
</tbody>
</table>
### Return Value | Meaning
--- | ---
EUNKNOWN | Unexpected exception.

#### EIMERR_LDAP_ERR (23)
Unexpected LDAP error.

#### EIMERR_UNKNOWN (44)
Unknown error or unknown system state.

### Example
The following example illustrates changing the description for the registry and enables the use of policy associations for the registry:

```c
#include <eim.h>
#include <string.h>
.
.
int           rc;
char          eimerr[200];
EimRC       * err;
EimHandle     handle;
.
.
/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Change the description for this registry */
rc = eimChangeRegistry(&handle,
    "MyAppRegistry",
    EIM_REGISTRY_DESCRIPTION,
    "New description",
    EIM_CHG,
    err);
.
.
/* reset error structure */
memset(eimerr,0x00,200);
err->memoryProvidedByCaller = 200;

/* Enable policy associations for this registry */
rc = eimChangeRegistry(&handle,
    "MyAppRegistry",
    EIM_REGISTRY_POLICY_ASSOCIATIONS,
    NULL,
    EIM_ENABLE,
    err);
.
.
```

### eimChangeRegistryAlias

#### Purpose
Adds or removes a registry alias for the defined registry.

Using registry aliases is one way to decouple registry names that developers use from the registry names that administrators choose. Developers who are designing applications know the registry type their application uses and choose the registry alias their program will use. Developers inform the administrator which registry types their applications use and the EIM registry aliases to associate with that registry type. The administrator adds the registry alias to the EIM registry of the appropriate type. The application can use the eimGetRegistryNameFromAlias API; given a registry alias, this API returns the registry name for the entry or entries with that registry alias.
### Format

```c
#include <eim.h>

int eimChangeRegistryAlias(EimHandle          * eim,
char               * registryName,
char               * aliasType,
char               * aliasValue,
enum EimChangeType  changeType,
EimRC              * eimrc)
```

### Parameters

**eim**

(Input) The EIM handle that a previous call to `eimCreateHandle` returns. A valid connection is required.

**registryName**

(Input) The name of the registry to change. Registry names are case-independent (meaning, not case-sensitive).

The following special characters are not allowed in registry names:

```
, = + < > # ; \ *
```

**aliasType**

(Input) A type of alias for this registry. The registry types that EIM provides include the following:

- `EIM_ALIASTYPE_DNS "DNSHostName"
- `EIM_ALIASTYPE_KERBEROS "KerberosRealm"
- `EIM_ALIASTYPE_ISSUER "IssuerDN"
- `EIM_ALIASTYPE_ROOT "RootDN"
- `EIM_ALIASTYPE_TCPIP "TCPIPAddress"
- `EIM_ALIASTYPE_LDAPDNSHOSTNAME "LdapDnsHostName"
- `EIM_ALIASTYPE_OTHER "Other"

To view the eim.h sample, refer to Chapter 12, “EIM header file and example,” on page 367. Users can define their own registry alias types. See “EIM registry definitions and aliasing” on page 13 for details.

**aliasValue**

(Input) The value for this alias.

**Note:** Do not include the asterisk (*) wild card character in names for registry aliases.

**changeType**

(Input) The type of change to make. This could be add or remove. Use `EIM_ADD(1)` to add an alias, and `EIM_RMV(2)` to remove an alias.

**eimrc**

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets `eimrc` with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

### Related Information

See the following:

- “eimGetRegistryNameFromAlias” on page 252
- “eimListRegistryAliases” on page 304
Authorization

EIM data
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM registries administrator
- EIM registry X administrator

z/OS authorization
No special authorization is necessary.

Return Values
The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<tr>
<td></td>
<td>No memory available. Unable to allocate required space.</td>
</tr>
</tbody>
</table>
Return Value | Meaning
---|---
ENOTCONN | LDAP connection has not been made. **EIMERR_NOT_CONN (31)** Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.
EROFS | LDAP connection is for read-only. Need to connect to master. **EIMERR_READ_ONLY (36)** This LDAP connection has "read-only" access. A connection to the master LDAP server with read/write is required to complete the operation. Use the eimConnectToMaster API to get a write connection.
EUNKNOWN | Unexpected exception. **EIMERR_LDAP_ERR (23)** Unexpected LDAP error. **EIMERR_UNKNOWN (44)** Unknown error or unknown system state.

### Example

The following example illustrates adding DNS and TCP/IP alias to the registry:

```c
#include <eim.h>

int rc;
char eimerr[200];
EimRC * err;
EimHandle handle;

/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Add a dns alias for this registry */
rc = eimChangeRegistryAlias(&handle,
"MyRegistry",
EIM_ALIASTYPE_DNS,
"Clueless",
EIM_ADD,
err);

/* Add a tcpip address as an alias */
rc = eimChangeRegistryAlias(&handle,
"MyRegistry",
EIM_ALIASTYPE_TCPIP,
"254.237.190.239",
EIM_ADD,
err);
```
eimChangeRegistryUser

Purpose
Changes the attributes for a target registry user.

There are situations when a mapping lookup operation can return more than one user. Applications can choose to use information in the additional information field to distinguish between returned target identities and determine which to use. For example, suppose Joe has two identities in a specific registry X, joeuser and joeadmin. An application provider can tell the administrator to add additional information, for example, "appname-admin," to the appropriate registry user -- in this case, joeadmin. The application can provide this additional information on the lookup APIs, eimGetTargetFromSource and eimGetTargetFromIdentifier.

Format

```c
#include <eim.h>

int eimChangeRegistryUser(EimHandle eim, char *registryName, char *registryUserName, enum EimRegistryUserAttr attrName, char *attrValue, enum EimChangeType changeType, EimRC *eimrc);
```

Parameters

eim
(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

registryName
(Input) The name of the registry that contains this user. Registry names are case-independent (meaning, not case-sensitive).

The following special characters are not allowed in registry names:

'\', '=', '+', '<', '>', '#', ';', '\', ' '*

registryUserName
(Input) The name of the user to change in this registry. The registry user name should begin with a non-blank character.

attrName
The attribute to update. Valid values are:

**EIM_REGISTRYUSER_DESCRIPTION (0)**
Change the registry description. Valid `changeType` is EIM_CHG (0).

**EIM_REGISTRYUSER_ADDL_INFO (1)**
Add or remove additional information for this user. You can have more than one AdditionalInfo field. Valid `changeType` is EIM_ADD (1) or EIM_RMV (2).

attrValue
(Input) The new value for the attribute. This value can be a NULL string (for example, "").

changeType
(Input) The type of change to make. This could be add, remove, or change. On z/OS, this can be one of the following:

**EIM_CHG (0)**
EIM sets the attribute to the new value. EIM creates the attribute if it does not already exist.
**EIM_ADD (1)**

EIM adds the attribute and its value to the identifier. EIM creates the attribute if it does not already exist.

**EIM_RMV (2)**

EIM removes the given attribute value from the attribute in the identifier entry. EIM removes the attribute itself from the entry if no values remain for the attribute. To remove the entire attribute, use NULL for the attribute value.

The attrName parameter indicates the type allowed for each attribute.

**eimrc**

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

See the following:

- “eimListRegistryUsers” on page 316

**Authorization**

**EIM data**

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM registries administrator
- EIM registry X administrator

**z/OS authorization**

No special authorization is needed.

</table>

**Example**

The following example illustrates changing the description and adding additional information for a target registry user.

```c
#include <eim.h>

int rc;
char eimerr[200];
EimRC * err;
```
EimHandle handle;

/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Change the registry user's description */
rc = eimChangeRegistryUser(&handle,
"MyRegistry",
"mjjones",
EIM_REGISTRYUSER_DESCRIPTION,
"cool customer",
EIM_CHG,
err);

/* Add additional information to the registry user*/
rc = eimChangeRegistryUser(&handle,
"MyRegistry",
"mjjones",
EIM_REGISTRYUSER_ADDL_INFO,
"security officer",
EIM_ADD,
err);

/* Add additional information to the registry user*/
rc = eimChangeRegistryUser(&handle,
"MyRegistry",
"mjjones",
EIM_REGISTRYUSER_ADDL_INFO,
"administrator",
EIM_ADD,
err);

eimConnect

Purpose
Connects to the EIM domain.

Format

#include <eim.h>

int eimConnect(EimHandle eim,
EimConnectInfo *connectInfo,
EimRC *eimrc)

Parameters

eim
(Input) The EIM handle that a previous call to eimCreateHandle returns.

connectInfo
(Input) Connect information. This parameter provides the information required to bind to LDAP. If the system is configured to connect to a secure port, EimSSLInfo is required.

For the EIM_SIMPLE connect type, the creds field should contain the EimSimpleConnectInfo structure with a binddn and password.

If the connect type is EIM_SIMPLE and you provide no binddn or password, the connection information extracted from the RACF database during the eimCreateHandle API call is used.

Note: Both the bindDn and bindPw must be NULL. Also, the previous call to eimCreateHandle must have been made with a NULL ldapURL in order for eimCreateHandle to have extracted the information from the RACF database. The resulting handle should then be used with eimConnect. If the ldapURL
was not NULL, then no information was extracted from the RACF database and a NULL bindDn and bindPw will result in an EIMERR_PARM_REQ error.

EimPasswordProtect determines the level of password protection on the LDAP bind.

**EIM_PROTECT_NO (0)**
- The clear-text password is sent on the bind.

**EIM_PROTECT_CRAM_MD5 (1)**
- The protected password is sent on the bind. The server side must support cram-md5 protocol to send the protected password.

**EIM_PROTECT_CRAM_MD5_OPTIONAL (2)**
- The protected password is sent on the bind if the cram-md5 protocol is supported. Otherwise, the clear-text password is sent.

For EIM_KERBEROS, the default logon credentials are used. The kerberos_creds field must be NULL.

For EIM_CLIENT_AUTHENTICATION, the creds field is ignored. The ssl field must point to a valid EimSSLInfo structure. The keyring field is required in the EimSSLInfo structure. It can be the name of a System SSL key database file or a RACF keyring name. The keyring_pw field is required when the keyring is the name of a System SSL key database field. The certificateLabel field is optional. If it is NULL the default certificate in the keyring is used.

The structure layouts follow:

```c
enum EimPasswordProtect {
    EIM_PROTECT_NO,
    EIM_PROTECT_CRAM_MD5,
    EIM_PROTECT_CRAM_MD5_OPTIONAL
};

enum EimConnectType {
    EIM_SIMPLE,
    EIM_KERBEROS,
    EIM_CLIENT_AUTHENTICATION
};

typedef struct EimSimpleConnectInfo {
    enum EimPasswordProtect protect;
    char * bindDn;
    char * bindPw;
} EimSimpleConnectInfo;

typedef struct EimSSLInfo {
    char * keyring;
    char * keyring_pw;
    char * certificateLabel;
} EimSSLInfo;

typedef struct EimConnectInfo {
    enum EimConnectType type;
    union {
        gss_cred_id_t * kerberos;
        EimSimpleConnectInfo simpleCreds;
    } creds;
    EimSSLInfo * ssl;
} EimConnectInfo;
```

**eimrc**
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

See the following:
Authorization

z/OS authorization
The calling application can be running in system key or supervisor state or one of the following:

- The RACF user ID of the caller’s address space has READ access to the BPX.SERVER profile in the FACILITY class
- The current RACF user ID has READ authority to the IRR.RDCEKEY profile in the FACILITY class

Applications that are not authorized (problem program state and keys) must be program controlled (exitattr +p) and the FACILITY class must be active and RACLISTed before the application will be granted authority to use this SAF service.

Return Values
The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>

</tr>
</tbody>
</table>

**Example**

The following example illustrates connecting to an EIM domain:

```c
#include <eim.h>
#include <string.h>
```
The following example illustrates connecting to an EIM domain using the default Kerberos credential for authentication:

```c
#include <eim.h>
#include <string.h>

int rc;
char eimerr[200];
EimRC *err;
EimHandle handle;

EimConnectInfo con;

/* Set up error structure. */
memset(eimerr, 0x00, 200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Set up connection information */
con.type = EIM_KERBEROS;
con.creds.simpleCreds.protect = EIM_PROTECT_NO;
con.creds.simpleCreds.bindDn = "cn=admin";
con.creds.simpleCreds.bindPw = "secret";
con.ssl = NULL;

/* Connect to LDAP URL defined by handle with specified connection credentials */
rc = eimConnect(&handle, con, err);
```

**Purpose**

Connects to the EIM master domain controller. You should use this API if an earlier API invocation returned a referral error (EROFS). A referral error indicates that the current EIM connection is to a replica system. To make updates, you must make an explicit connection to the master system. If the host system
is not a replica, then the master information retrieved is the same as the host and port defined in the handle.

Format

```
#include <eim.h>

int eimConnectToMaster(EimHandle *eim, 
                       EimConnectInfo *connectInfo, 
                       EimRC *eimrc)
```

Parameters

**eim**

(Input) The EIM handle that a previous call to eimCreateHandle returns.

**connectInfo**

(Input) Connect information. This parameter provides the information required to bind to LDAP. If the system is configured to connect to a secure port, EimSSLInfo is required.

For the EIM_SIMPLE connect type, the creds field should contain the EimSimpleConnectInfo structure with a binddn and password.

On z/OS, if the connect type is EIM_SIMPLE and you provide no bindDn or bindPw, the connection information extracted from the RACF database during the eimCreateHandle API call is used.

**Note:** Both the bindDn and bindPw must be NULL. Also, the previous call to eimCreateHandle must have been made with a NULL ldapURL in order for eimCreateHandle to have extracted the information from the RACF database. The resulting handle should then be used with eimConnectToMaster. If the ldapURL was not NULL, then no information was extracted from the RACF database and a NULL bindDn and bindPw will result in an EIMERR_PARM_REQ error.

EimPasswordProtect determines the level of password protection on the LDAP bind.

**EIM_PROTECT_NO (0)**

The clear-text password is sent on the bind.

**EIM_PROTECT_CRAM_MD5 (1)**

The protected password is sent on the bind. The server side must support cram-md5 protocol to send the protected password.

**EIM_PROTECT_CRAM_MD5_OPTIONAL (2)**

The protected password is sent on the bind if the cram-md5 protocol is supported.

For EIM_KERBEROS, the default logon credentials are used. The kerberoscreds field must be NULL.

For EIM_CLIENT_AUTHENTICATION, the creds field is ignored. The ssl field must point to a valid EimSSLInfo structure. The keyring field is required in the EimSSLInfo structure. It can be the name of a System SSL key database file or a RACF keyring name. The keyring_pw field is required when the keyring is the name of a System SSL key database field. The certificateLabel field is optional. If it is NULL the default certificate in the keyring is used.

The structure layouts follow:

```c
enum EimPasswordProtect {
   EIM_PROTECT_NO, 
   EIM_PROTECT_CRAM_MD5, 
   EIM_PROTECT_CRAM_MD5_OPTIONAL
};

denum EimConnectType {
   EIM_SIMPLE, 
   EIM_KERBEROS, 
   EIM_CLIENT_AUTHENTICATION
};
```
typedef struct EimSimpleConnectInfo
{
    enum EimPasswordProtect protect;
    char * bindDn;
    char * bindPw;
} EimSimpleConnectInfo;

typedef struct EimSSLInfo
{
    char * keyring;
    char * keyring_pw;
    char * certificateLabel;
} EimSSLInfo;

typedef struct EimConnectInfo
{
    enum EimConnectType type;
    union {
        gss_cred_id_t * kerberos;
        EimSimpleConnectInfo simpleCreds;
    } creds;
    EimSSLInfo * ssl;
} EimConnectInfo;

**eimrc**

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

See the following:

- “eimConnect” on page 210
- “eimCreateHandle” on page 223
- “eimDestroyHandle” on page 231
- “eimGetAttribute” on page 249
- “eimSetAttribute” on page 354

**Authorization**

**z/OS authorization**

The calling application can be running in system key or supervisor state or one of the following:

- The RACF user ID of the caller’s address space has READ access to the BPX.SERVER profile in the FACILITY class
- The current RACF user ID has READ authority to the IRR.RDCEKEY profile in the FACILITY class

Applications that are not authorized (problem program state and keys) must be program controlled (extattr +p) and the FACILITY class must be active and RACLISTERd before the application will be granted authority to use this SAF service.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>

</table>

**Example**

The following example illustrates connecting to an EIM master domain:

```c
#include <eim.h>
#include <string.h>

int rc;
char eimerr[200];
EimRC *err;
EimHandle handle;
EimConnectInfo con;

/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Set up connection information */
con.type = EIM_SIMPLE;
con.creds.simpleCreds.protect = EIM_PROTECT_NO;
con.creds.simpleCreds.bindDn = "cn=admin";
con.creds.simpleCreds.bindPw = "secret";
con.ssl = NULL;

/* Connect to master LDAP URL defined in handle with the specified connection credentials */
rc = eimConnectToMaster(&handle, con, err);
```

The following example illustrates connecting to an EIM master domain using client authentication, referencing the default digital certificate in a key database file:

```c
#include <eim.h>
#include <string.h>

int rc;
char eimerr[200];
EimRC *err;
EimHandle handle;
EimConnectInfo con;
EimSSLInfo sslinfo;
```
eimCreateDomain

Purpose
Creates an EIM domain on the specified EIM domain controller.

Format

```c
#include <eim.h>

int eimCreateDomain(char            *ldapURL, EimConnectInfo connectInfo, char           *description, EimRC          *eimrc)
```

Parameters

- **ldapURL**
  (Input) A uniform resource locator (URL) that contains the EIM host information. This parameter is required. This URL has the following format:

  ```
  ldap://host:port/dn
  ```

  or

  ```
  ldaps://host:port/dn
  ```

- **host:port**
  Name of the host on which the EIM domain controller is running. (The port number is optional. If not specified, the default LDAP or LDAPS port will be used.)

- **dn**
  Distinguished name of the domain to create.

Example:

```bash
ldap://systemx:389/ibm-eimDomainName=myEimDomain,o=myCompany,c=us
ldap://systemy:636/ibm-eimDomainName=thisEimDomain,o=myCompany,c=us
```
**Note:** In contrast with ldap, ldaps indicates that this host and port combination uses SSL and TLS.

**connectInfo**
(Input) Connect information. This parameter provides the information required to bind to LDAP. If the system is configured to connect to a secure port, EimSSLInfo is required.

For the EIM_SIMPLE connect type, the creds field should contain the EimSimpleConnectInfo structure with a binddn and password.

EimPasswordProtect determines the level of password protection on the LDAP bind.

**EIM_PROTECT_NO (0)**
The clear-text password is sent on the bind.

**EIM_PROTECT_CRAM_MD5 (1)**
The protected password is sent on the bind. The server side must support cram-md5 protocol to send the protected password.

**EIM_PROTECT_CRAM_MD5_OPTIONAL (2)**
The protected password is sent on the bind if the cram-md5 protocol is supported. Otherwise, the clear-text password is sent.

For EIM_KERBEROS, the default logon credentials are used. The kerberos_creds field must be NULL.

For EIM_CLIENT_AUTHENTICATION, the creds field is ignored. The ssl field must point to a valid EimSSLInfo structure. The keyring field is required in the EimSSLInfo structure. It can be the name of a System SSL key database file or a RACF keyring name. The keyring_pw field is required when the keyring is the name of a System SSL key database field. The certificateLabel field is optional. If it is NULL the default certificate in the keyring is used.

The structure layouts follow:

```c
enum EimPasswordProtect {
    EIM_PROTECT_NO,
    EIM_PROTECT_CRAM_MD5,
    EIM_PROTECT_CRAM_MD5_OPTIONAL
};
enum EimConnectType {
    EIM_SIMPLE,
    EIM_KERBEROS,
    EIM_CLIENT_AUTHENTICATION
};
typedef struct EimSimpleConnectInfo {
    enum EimPasswordProtect protect;
    char * bindDn;
    char * bindPw;
} EimSimpleConnectInfo;
typedef struct EimSSLInfo {
    char * keyring;
    char * keyring_pw;
    char * certificateLabel;
} EimSSLInfo;
typedef struct EimConnectInfo {
    enum EimConnectType type;
    union {
        gss_cred_id_t * kerberos;
        EimSimpleConnectInfo simpleCreds;
    } creds;
    EimSSLInfo * ssl;
} EimConnectInfo;
```

**description**
(Input) Textual description for the new EIM domain entry. This parameter can be NULL.
**eimrc**

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

See the following:

- “eimChangeDomain” on page 191
- “eimDeleteDomain” on page 227
- “eimListDomains” on page 281

**Authorization**

**EIM data**

LDAP administrators have the authority to create an EIM domain.

**z/OS authorization**

No special authorization is needed.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

</table>
### Return Value | Meaning
---|---
EUNKNOWN | Unexpected exception.
**EIMERR_LDAP_ERR (23)** | Unexpected LDAP error.
**EIMERR_UNKNOWN (44)** | Unknown error or unknown system state.

### Example

The following example creates an EIM domain with the name of `myEIMDomain`. The distinguished name for the domain after it is created will be: "ibm-eimDomainName=myEIMDomain,o=mycompany,c=us".

```c
#include <eim.h>
#include <stdio.h>
#include <string.h>

int main(int argc, char *argv[])
{
    int            rc;
    char          eimerr[200];
    EimRC       * err;

    char * ldapURL =
        "ldap://eimsystem:389/ibm-eimDomainName=myEimDomain,o=mycompany,c=us";

    EimConnectInfo con;
    /* Set up connection information */
    con.type = EIM_SIMPLE;
    con.creds.simpleCreds.protect = EIM_PROTECT_NO;
    con.creds.simpleCreds.bindDn = "cn=admin";
    con.creds.simpleCreds.bindPw = "secret";
    con.ssl = NULL;

    /* Set up error structure. */
    memset(eimerr,0x00,200);
    err = (EimRC *)eimerr;
    err->memoryProvidedByCaller = 200;

    /* Create a new EIM domain */
    if (0 != (rc = eimCreateDomain(ldapURL,
                                    con,
                                    NULL,
                                    err)))
        printf("Create domain error = %d", rc);

    return 0;
}
```

---

**eimCreateHandle**

### Purpose

Allocates an EimHandle structure, which is used to identify the EIM connection and to maintain per-connection information. The EimHandle structure is passed on subsequent calls to other EIM operations.

### Format

```c
#include <eim.h>

int eimCreateHandle(EimHandle      * eim,
                     char           * ldapURL,
                     EimRC          * eimrc)
```
eimCreateHandle

Parameters

**eim**
(Output) The pointer to an EIM handle to return. This handle is input for other EIM APIs.

**ldapURL**
A NULL parameter indicates the ldapURL information is retrieved from a RACF profile. eimCreateHandle uses the LDAP host name and domain distinguished name stored in the profile to create the ldapURL. The eimCreateHandle retrieves the information from one of the following profiles in this order:

1. The LDAPBIND class profile associated with the caller's user profile
2. The IRR.EIM.DEFAULTS profile in the LDAPBIND class
3. The system default profile, IRR.PROXY.DEFAULTS profile in the FACILITY class

This URL has the following format:

```
ldap://host:port/dn
ldaps://host:port/dn
```

**host:port**
Name of the host on which the EIM domain controller is running. (The port number is optional. If not specified, the default LDAP or LDAPS port will be used.)

**dn**
Distinguished name of the domain to change.

**Example:**

```
ldap://systemx:389/ibm-eimDomainName=myEimDomain,o=myCompany,c=us
ldaps://systemy:636/ibm-eimDomainName=thisEimDomain,o=myCompany,c=us
```

**Note:** In contrast with ldap, ldaps indicates that this host and port combination uses SSL and TLS.

**eimrc**
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information

- “eimConnectToMaster” on page 214
- “eimDestroyHandle” on page 231
- “eimGetAttribute” on page 249
- “eimSetAttribute” on page 354

Authorization

**z/OS authorization**

The calling application can be running in system key or supervisor state or one of the following:

- The RACF user ID of the caller's address space has READ authority to the BPX.SERVER profile in the FACILITY class
- The current RACF user ID has READ authority to the IRR.RGETINFO.EIM profile in the FACILITY class

The FACILITY class must be active and RACLISTed before unauthorized (problem program state and keys) will be granted the authority to use this SAF service.
## Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the `messageCatalogMessageID` field in the `eimrc` parameter for that value.

<table>

<td>Unknown error or unknown system state.</td>
</tr>
</tbody>
</table>

**Example**

The following example illustrates creating an EIM handle with an LDAP URL and using information stored in a RACF profile.

```c
#include <eim.h>

int rc; 
char eimerr[200]; 
EimRC * err; 
EimHandle handle; 
EimHandle handle2; 
char * ldapURL = "ldap://eimsystem:389/ibm-eimDomainName=myEimDomain,o=mycompany,c=us";

/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Create a new eim handle using stored LDAP host and DomainDN in RACF profile */
r = eimCreateHandle(&handle, NULL, err);

/* Create a new eim handle using a specified URL */
r = eimCreateHandle(&handle2, ldapURL, err);
```

226  z/OS: Integrated Security Services Enterprise Identity Mapping (EIM) Guide and Reference
Purpose

Deletes the EIM domain information. If there are any registries or identifiers in the domain, then it cannot be deleted.

Format

```c
#include <eim.h>

int eimDeleteDomain(char *ldapURL, EimConnectInfo *connectInfo, EimRC *eimrc)
```

Parameters

**ldapURL**

(Input) A uniform resource locator (URL) that contains the EIM host information. This parameter is required. This URL has the following format:

- `ldap://host:port/dn`
- `ldaps://host:port/dn`

**host:port**

Name of the host on which the EIM domain controller is running. (The port number is optional. If not specified, the default LDAP or LDAPS port will be used.)

**dn**

Distinguished name of the domain to delete.

**Example:**

```plaintext
ldap://systemx:389/ibm-eimDomainName=myEimDomain,o=myCompany,c=us
ldaps://systemy:636/ibm-eimDomainName=thisEimDomain,o=myCompany,c=us
```

**Note:** In contrast with ldap, ldaps indicates that this host and port combination uses SSL and TLS.

**connectInfo**

(Input) Connect information. This parameter provides the information required to bind to LDAP. If the system is configured to connect to a secure port, EimSSLInfo is required.

For the EIM_SIMPLE connect type, the creds field should contain the EimSimpleConnectInfo structure with a binddn and password.

EimPasswordProtect determines the level of password protection on the LDAP bind.

**EIM_PROTECT_NO (0)**

The clear-text password is sent on the bind.

**EIM_PROTECT_CRAM_MD5 (1)**

The protected password is sent on the bind. The server side must support cram-md5 protocol to send the protected password.

**EIM_PROTECT_CRAM_MD5_OPTIONAL (2)**

The protected password is sent on the bind if the cram-md5 protocol is supported. Otherwise, the clear-text password is sent.

For EIM_KERBEROS, the default logon credentials are used. The kerberos_creds field must be NULL.
For EIM_CLIENT_AUTHENTICATION, the creds field is ignored. The ssl field must point to a valid EimSSLInfo structure. The keyring field is required in the EimSSLInfo structure. It can be the name of a System SSL key database file or a RACF keyring name. The keyring_pw field is required when the keyring is the name of a System SSL key database field. The certificateLabel field is optional. If it is NULL the default certificate in the keyring is used.

The structure layouts follow:

```c
enum EimPasswordProtect {
    EIM_PROTECT_NO,
    EIM_PROTECT_CRAM_MD5,
    EIM_PROTECT_CRAM_MD5_OPTIONAL
};
enum EimConnectType {
    EIM_SIMPLE,
    EIM_KERBEROS,
    EIM_CLIENT_AUTHENTICATION
};
typedef struct EimSimpleConnectInfo {
    enum EimPasswordProtect protect;
    char * bindDn;
    char * bindPw;
} EimSimpleConnectInfo;
typedef struct EimSSLInfo {
    char * keyring;
    char * keyring_pw;
    char * certificateLabel;
} EimSSLInfo;
typedef struct EimConnectInfo {
    enum EimConnectType type;
    union {
        gss_cred_id_t * kerberos;
        EimSimpleConnectInfo simpleCreds;
    } creds;
    EimSSLInfo * ssl;
} EimConnectInfo;
```

eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information
See the following:
- “eimCreateDomain” on page 219
- “eimChangeDomain” on page 191
- “eimListDomains” on page 281

Authorization
EIM data
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:
- EIM administrator

z/OS authorization
No special authorization is needed.
### Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the `messageCatalogMessageID` field in the `eimrc` parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>

<td>Unexpected LDAP error.</td>
</tr>
<tr>
<td><strong>EIMERR_UNKNOWN (44)</strong></td>
<td>Unknown error or unknown system state.</td>
</tr>
</tbody>
</table>

**Example**

The following example deletes the specified EIM domain information:

```c
#include <eim.h>
#include <string.h>

int main(int argc, char *argv[])
{
    int           rc;
    char          eimerr[200];
    EimRC       * err;
    char * ldapURL =
        "ldap://eimsystem:389/ibm-eimDomainName=myEimDomain,o=mycompany,c=us";
    EimConnectInfo con;

    /* Set up connection information */
    con.type = EIM_SIMPLE;
    con.creds.simpleCreds.protect = EIM_PROTECT_NO;
    con.creds.simpleCreds.bindDn = "cn=admin";
    con.creds.simpleCreds.bindPw = "secret";
    con.ssl = NULL;

    /* Set up error structure. */
    memset(eimerr,0x00,200);
    err = (EimRC *)eimerr;
    err->memoryProvidedByCaller = 200;

    /* Delete this domain */
    if (0 != (rc = eimDeleteDomain(ldapURL,
        con,
        err)))
        printf("Delete domain error = %d", rc);
    return 0;
}
```
Purpose
Frees resources associated with the EimHandle and closes connections to the EIM domain controllers. This closes the EIM connection for this handle.

Format
```c
#include <eim.h>

int eimDestroyHandle(EimHandle      * eim,
                       EimRC          * eimrc)
```

Parameters
- **eim**
  (Input) The EIM handle that a previous call to eimCreateHandle returns.
- **eimrc**
  (Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information
See the following:
- “eimConnect” on page 210
- “eimConnectToMaster” on page 214
- “eimCreateHandle” on page 223
- “eimGetAttribute” on page 249
- “eimSetAttribute” on page 354

Authorization
z/OS authorization
No special authorization is needed.

Return Values
The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the `eimrc` parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>
</tr>
<tr>
<td>EBADDATA</td>
<td>eimrc is not valid.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>Unable to allocate internal system object.</td>
</tr>
<tr>
<td>EIMERR_NOLOCK (26)</td>
<td>(z/OS does not return this value.) Unable to allocate internal system object.</td>
</tr>
</tbody>
</table>
### Return Value | Meaning
--- | ---
EINVAL | Input parameter was not valid.

**EIMERR_HANDLE_INVAL (17)**
EimHandle is not valid.

**EIMERR_PARM_REQ (34)**
Missing required parameter. Please check the API documentation.

**EIMERR_PTR_INVAL (35)**
(z/OS does not return this value.) Pointer parameter is not valid.

EUNKNOWN | Unexpected exception.

**EIMERR_UNKNOWN (44)**
Unknown error or unknown system state.

### Example
The following example illustrates destroying an EIM handle:

```c
#include <eim.h>

int rc;
char eimerr[200];
EimRC * err;
EimHandle * handle;

/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Destroy the handle */
rc = eimDestroyHandle(handle, err);
```

---

### eimErr2String

**Purpose**
Converts the EIM return code structure that an EIM function returns into a NULL-terminated character string that describes the error.

**Format**

```c
#include <eim.h>

char * eimErr2String(EimRC * eimrc)
```
Parameters

*eimrc*

(Input) The structure in which to return error code information. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Authorization

z/OS authorization

None.

Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the *eimrc* parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>address of error string</td>
<td>Request was successful. (The caller is expected to free the error string.)</td>
</tr>
<tr>
<td>NULL</td>
<td>Request was unsuccessful. The eimErr2String sets global errno. The errno can be set by catopen, catgets, catclose, or one of the following values:</td>
</tr>
<tr>
<td>EBADDATA</td>
<td>eimrc is not valid. No eimrc structure was provided or the eimrc is not large enough to be an eimrc structure.</td>
</tr>
</tbody>
</table>

Example

The following example converts an EIM RC into an error message and prints it.

```c
#include <eim.h>
#include <stdio.h>

... char eimerr[150]; EimRC * err; char * message;

... /* Set up error structure. */ memset(eimerr,0x00,150); err = (EimRC *)eimerr; err->memoryProvidedByCaller = 150;

/* Call an EIM API that returns an EimRC...*/

if (NULL == (message = eimErr2String(err)))

int eimFormatPolicyFilter(EimUserIdentityInfo  * userIdentityInfo,
                          EimPolicyFilterSubsetInfo  * subsetInfo,
                          unsigned int              lengthOfListData,
                          EimList                    * listData,
                          EimRC                      * eimrc)

## Parameters

**userIdentityInfo**
(Input) The user identity information from which to generate policy filter values. This structure contains information about the user identity. For EIM_DER_CERT (0) or EIM_BASE64_CERT (1) user identity type, the userIdentityInfo field must contain an EimCertificate structure. For EIM_CERT_INFO (2) user identity type, the userIdentityInfo field must contain an EimCertificateInfo structure.

The structure layouts follow:

```c
enum EimUserIdentityType {
  EIM_DER_CERT,               /* Entire X.509 public key 
                             /* certificate in ASN.1 DER encoding,
                             /* Public Key Cryptography      
                             /* Standard 6 (PKCS-6) or PKCS-7 format. */
  EIM_BASE64_CERT,            /* Base 64 encoded version of the 
                             /* entire X.509 public key   
                             /* certificate in ASN.1 DER    
                             /* encoding, Public Key        
                             /* Cryptography Standard 6 (PKCS-6) or PKCS-7 format. */
  EIM_CERT_INFO               /* Components of the certificate. */
};

typedef struct EimCertificateInfo {
  char        * issuerDN;         /* The issuer DN.                 */
  char        * subjectDN;        /* The subject DN.                */
  void char   * publicKey;        /* The public key info structure (may be NULL). */
  unsigned int  publicKeyLen;     /* Length of public key info structure (may be 0)*/
} EimCertificateInfo;

typedef struct EimCertificate {
  char        * certData;         /* The certificate data           */
  unsigned int certLength;        /* The length of the certificate   
                             /* data.                          */
} EimCertificate;

typedef struct EimUserIdentityInfo {
  enum EimUserIdentityType type;
  union {
    EimCertificateInfo certInfo;
    EimCertificate    cert;
  } userIdentityInfo;
} EimUserIdentityInfo;
```

**subsetInfo**
(Input) The information used to subset the policy filter values that are formatted. If NULL is specified, then all possible return values are returned for the specified user identity. If this parameter is not NULL, then the results returned are based on the subset information. For EIM_BASE64_CERT (0), EIM_DER_CERT (1), or EIM_CERT_INFO (2) user identity type, the subset field must contain an EimCertPolicyFilterSubsetInfo structure.

The structure layouts follow:

```c
typedef struct EimCertPolicyFilterSubsetInfo {
  char         * subjectFilter; /* Subject filter value. */
  char         * issuerFilter;  /* Issuer filter value. */
} EimCertPolicyFilterSubsetInfo;

typedef struct EimPolicyFilterSubsetInfo {
  union {
    EimCertPolicyFilterSubsetInfo certFilter;
    EimPolicyFilterSubsetInfo    certFilter;
  } eimrc;
} EimPolicyFilterSubsetInfo;
```
lengthOfListData
(Input) The number of bytes provided by the caller for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. The minimum size required is 20 bytes.

listData
(Output) A pointer to the EimList structure, which contains information about the returned data. The data takes the form of a linked list of EimPolicyFilterValue structures.

The EimList structure has the following layout:

```c
typedef struct EimList
{
    unsigned int bytesReturned;     /* Number of bytes actually returned
                                    by the API */
    unsigned int bytesAvailable;    /* Number of bytes of available data
                                    that could have been returned by
                                    the API */
    unsigned int entriesReturned;   /* Number of entries actually
                                    returned by the API */
    unsigned int entriesAvailable;  /* Number of entries available to be
                                    returned by the API */
    unsigned int firstEntry;        /* Displacement to the first linked
                                    list entry. This byte offset is
                                    relative to the start of the
                                    EimList structure. */
} EimList;
```

The EimPolicyFilterValue structure has the following layout:

```c
typedef struct EimPolicyFilterValue
{
    unsigned int nextEntry; /* Displacement to next entry. This byte offset is relative to the
                              start of this structure */
    EimListData filterValue; /* Generated policy filter value. */
} EimPolicyFilterValue;
```

The EimListData structure has the following layout:

```c
typedef struct EimListData
{
    unsigned int length; /* Length of data */
    unsigned int disp;   /* Displacement to data. This byte offset is relative to the start of the
                          parent structure; that is, the structure containing this structure. */
} EimListData;
```

eimrc
(Input) The structure in which to return error code information. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

### Example

The following example generates certificate policy filter values.

```c
#include <eim.h>
#include <stdio.h>
#include <stddef.h>
#include <string.h>
#include <sys/stat.h>
#include <errno.h>

void printListResults(EimList * list);
void printListData(char * fieldName, void * entry, int offset);

int main (int argc, char *argv[])
{
    int                  rc;
    char                 eimerr[250];
    EimRC              * err;
    EimHandle          * handle;
```

    }
}

eimFormatUserIdentity

Purpose

Takes unformatted user identity information and formats it for use with other EIM functions.

Format

#include <eim.h>
int eimFormatUserIdentity(        enum EimUserIdentityFormatType formatType,
Parameters

**formatType**
(Input) How to format the user identity. Choices for input are:

**EIM_REGISTRY_USER_NAME (0)**
Indicates the user identity information be used to form a registry user name that may then be used as a registryUserName on other EIM APIs. For certificates or certificate information, the registry user name is formed from the subject distinguished name (SDN), issuer distinguished name (IDN), and a hash of the public key information. The registry user name takes this format:

<SDN>subject-DN</SDN><IDN>issuer-DN</IDN><HASH_VAL>hash-value</HASH_VAL>

**userIdentityInfo**
(Input) The user identity information to format. For EIM_DER_CERT (0) or EIM_BASE64_CERT (1) user identity type, the userIdentityInfo field must contain an EimCertificate structure. For EIM_CERT_INFO (2) user identity type, the userIdentityInfo field must contain an EimCertificateInfo structure.

The structure layouts follow:

```c
enum EimUserIdentityType {
    EIM_DER_CERT,                   /* Entire X.509 public key certificate in ASN.1 DER encoding, Public Key Cryptography Standard 6 (PKCS-6) or PKCS-7 format. */
    EIM_BASE64_CERT,                /* Base 64 encoded version of the entire X.509 public key certificate in ASN.1 DER encoding, Public Key Cryptography Standard 6 (PKCS-6) or PKCS-7 format. */
    EIM_CERT_INFO                   /* Components of the certificate. */
};
typedef struct EimCertificateInfo {
    char * issuerDN;         /* The issuer DN. */
    char * subjectDN;        /* The subject DN. */
    void * publicKey;        /* The public key info structure. */
    unsigned int  publicKeyLen;     /* Length of public key info structure. */
} EimCertificateInfo;
typedef struct EimCertificate {
    unsigned int certLength;        /* The length of the certificate data. */
    char * certData;         /* The certificate data */
} EimCertificate;
typedef struct EimUserIdentityInfo {
    enum EimUserIdentityType type;
    union {
        EimCertificateInfo certInfo;
        EimCertificate  cert;
    } userIdentityInfo;
} EimUserIdentityInfo;
```

If the userIdentityInfo field contains an EimCertificateInfo structure, the issuerDN and subjectDN fields must contain valid DN strings (for example CN=John D. Smith,OU=Sales,O=IBM,L=Rochester,ST=Min,C=US). The PublicKey field must contain the full DER encoded public key information structure, and the publicKeyLen field must contain the length of that structure.

For EIM_DER_CERT (0) certifications, certData must point to a buffer containing the DER encoded cert and the certLength field must contain the length of the certificate. The length specified in certLength will be verified against the length encoded in the certificate.
For EIM_BASE64_CERT (1) certificates, certData must point to a buffer containing the base64 encoded certificate with or without the BEGIN - END tags removed and certLength must contain the length of certData.

**lengthOfUserIdentity**
(Input) The number of bytes provided by the caller for the formatted user identity. The size required is calculated as: the length of the subject DN, plus the length of the issuer DN, plus 40 bytes for the hash value, plus 43 bytes for the SDN, IDN and HASH_VAL tags, plus 16 bytes for the other elements of the EimUserIdentity structure. The minimum size is 16 bytes.

**userIdentity**
(Output) A pointer to the data to be returned. The API will return as much data as the space allows.

EimUserIdentity has the following structure:

```c
typedef struct EimUserIdentity
{
    unsigned int bytesReturned;     /* Number of bytes actually returned by the API.                      */
    unsigned int bytesAvailable;    /* Number of bytes of available data that could have been returned by the API. */
    EimListData  userIdentity;      /* User identity                  */
} EimUserIdentity;
```

EimListData has the following structure:

```c
typedef struct EimListData
{
    unsigned int length;            /* Length of data                 */
    unsigned int disp;              /* Displacement to data. This byte offset is relative to the start of the parent structure; that is, the structure containing this structure. */
} EimListData;
```

**eimrc**
(Input) The structure in which to return error code information. If the return value is not 0, eimrc is set with additional information. This parameter may be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

        err))){
        printf("Format user identity error = %d\n", rc);
        free(certBuf);
        return -1;
    } else {
        printf("Formatted user identity: %s\n", (char *)fmtData + fmtData->userIdentity.disp);
    }
    free(certBuf);
    return 0;
}
eimGetAssociatedIdentifiers

Purpose
Returns a list of the identifiers. Given a registry name and registry user name within that user registry, this API returns the EIM identifier associated with it. It is possible that more than one person is associated with a specific user name. This occurs when users share identities (and possibly passwords) within a single instance of a user registry. While this practice is not condoned, it does happen. This creates an ambiguous result.

Format
```
#include <eim.h>

int eimGetAssociatedIdentifiers(EimHandle *eim, 
    enum EimAssociationType *associationType, 
    char *registryName, 
    char *registryUserName, 
    unsigned int *lengthOfListData, 
    EimList *listData, 
    EimRC *eimrc)
```

Parameters
eim
(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

associationType
(Input) The type of association to retrieve. Valid values are:

- **EIM_ALL_ASSOC (0)**
  Retrieve all associations.
- **EIM_TARGET (1)**
  Retrieve target associations.
- **EIM_SOURCE (2)**
  Retrieve source associations.
- **EIM_SOURCE_AND_TARGET (3)**
  Retrieve source and target associations.
- **EIM_ADMIN (4)**
  Retrieve administrative associations.

registryName
(Input) The registry name for the lookup. If this string has a null value, the API uses the system default local registry name from the instorage copy of the registry name. Registry names are case-independent (meaning, not case-sensitive).

The following special characters are not allowed in registry names:
```
, = + > # ; \ *
```

registryUserName
(Input) The registry user name for the lookup.

lengthOfListData
(Input) The number of bytes provided by the caller for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. The minimum size required is 20 bytes.
**listData**

(Output) A pointer to the data to return. The EimList structure contains information about the returned data. The data returned is a linked list of EimIdentifier structures. The firstEntry is used to get to the first EimIdentifier structure in the linked list. The number of complete EimIdentifier structures is returned in entriesReturned. The bytesReturned variable has the number of bytes the API used for the returned entries. If the number of entries returned is less than the number of entries available, the returned data contains as many complete EimIdentifier structures as will fit. It can also contain a partial EimIdentifier structure. The EimList structure follows:

```c
typedef struct EimList
{
    unsigned int bytesReturned; /* Number of bytes actually returned by the API */
    unsigned int bytesAvailable; /* Number of bytes of available data that could have been returned by the API */
    unsigned int entriesReturned; /* Number of entries actually returned by the API */
    unsigned int entriesAvailable; /* Number of entries available to be returned by the API */
    unsigned int firstEntry; /* Displacement to the first linked list entry. This byte offset is relative to the start of the EimList structure. */
} EimList;
```

The EimIdentifier structure follows:

```c
typedef struct EimIdentifier
{
    unsigned int nextEntry; /* Displacement to next entry. This byte offset is relative to the start of this structure */
    EimListData uniquename; /* Unique name */
    EimListData description; /* Description */
    EimListData entryUUID; /* UUID */
    EimSubList names; /* EimIdentifierName sublist */
    EimSubList additionalInfo; /* EimAddlInfo sublist */
} EimIdentifier;
```

Identifiers might have defined several name attributes as well as several additional information attributes. In the EimIdentity structure, the name EimSubList gives addressability to a linked list of EimIdentifierName structures:

```c
typedef struct EimIdentifierName
{
    unsigned int nextEntry; /* Displacement to next entry. This byte offset is relative to the start of this structure */
    EimListData name; /* Name */
} EimIdentifierName;
```

The additionalInfo EimSubList gives addressability to a linked list of EimAddlInfo structures. The EimAddlInfo structure follows:

```c
typedef struct EimAddlInfo
{
    unsigned int nextEntry; /* Displacement to next entry. This byte offset is relative to the start of this structure */
    EimListData addlInfo; /* Additional info */
} EimAddlInfo;
```

The EimSubList structure follows:

```c
typedef struct EimSubList
{
    unsigned int listNum; /* Number of entries in the list */
    unsigned int disp; /* Displacement to sublist. This byte offset is relative to the start of the parent structure, i.e. the structure containing this
```
The EimListData structure follows:

```c
typedef struct EimListData {
    unsigned int length;            /* Length of data                 */
    unsigned int disp;              /* Displacement to data.  This byte
                                           offset is relative to the start of
                                           the parent structure, i.e. the
                                           structure containing this
                                           structure.                       */
} EimListData
```

**eimrc**

(Input/output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see "EimRC -- EIM return code parameter for C/C++" on page 166.

**Related Information**

See the following:

- “eimAddIdentifier” on page 178
- “eimChangeIdentifier” on page 196
- “eimListIdentifiers” on page 287
- “eimRemoveIdentifier” on page 337

**Authorization**

**EIM data**

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM registries administrator
- EIM identifiers administrator
- EIM mapping-lookup authority
- EIM registry X administrator

The returned list contains only the information that the user has authority to access.

**z/OS authorization**

The calling application can be running in system key or supervisor state or one of the following:

- The RACF user ID of the caller's address space has READ authority to the BPX.SERVER profile in the FACILITY class
- The current RACF user ID has READ authority to the IRR.RGETINFO.EIM profile in the FACILITY class

The FACILITY class must be active and RACLISTed before unauthorized (problem program state and keys) will be granted the authority to use this SAF service.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>

    if (dataLength > 0)
        printf(\"%.*s\n\", dataLength, data);
    else
        printf(\"Not found.\n\");
eimGetAttribute

Purpose

Gets attributes for this EIM handle. If the host system for the EIM domain is a replica LDAP server, the handle master attributes contain the host system information for the master LDAP server. If the host system for the EIM domain is a master (meaning it is writable) LDAP server, the HOST, PORT and SECPORT handle attributes and master handle attributes have the same values.

Format

```c
#include <eim.h>

int eimGetAttribute(EimHandle          *eim,
enum EimHandleAttr attrName,
unsigned int        lengthOfEimAttribute,
EimAttribute       *attribute,
EimRC              *eimrc)
```

Parameters

**eim**

(Input) The EIM handle that a previous call to eimCreateHandle returns.

**attrName**

(Input) The name of the attribute to retrieve. The following values are valid:

- **EIM_HANDLE_CCSID (0)**
  
  (z/OS does not support this value.) This is the coded character set identifier (CCSID) of character data that the caller of EIM APIs passes with the specified EimHandle. The returned field is a 4-byte integer.

- **EIM_HANDLE_DOMAIN (1)**
  
  The EIM domain name.

- **EIM_HANDLE_HOST (2)**
  
  The host system for the EIM domain.

- **EIM_HANDLE_PORT (3)**
  
  The port for the EIM connection. The returned field is a 4-byte integer.

- **EIM_HANDLE_SECPORT (4)**
  
  Security type for this connection. The returned field is a 4-byte integer. Possible values are:

  0
  
  Non-SSL

  1
  
  Port uses SSL

- **EIM_HANDLE_MASTER_HOST (5)**

  If the EIM_HANDLE_HOST is a replica LDAP server, this value indicates the master LDAP server.

- **EIM_HANDLE_MASTER_PORT (6)**

  If the EIM_HANDLE_HOST is a replica LDAP server, this value indicates the port for the master LDAP server. The returned field is a 4-byte integer.

- **EIM_HANDLE_MASTER_SECPORT (7)**

  If the EIM_HANDLE_HOST is a replica LDAP server, this value indicates the security type for the master LDAP server. The returned field is a 4-byte integer. Possible values are:
eimGetAttribute

0  Non-SSL
1  Port uses SSL

**lengthOfEimAttribute**
(Input) The number of bytes the caller provides for the attribute information. The minimum size required is 16 bytes.

**attribute**
(Output) A pointer to the data to return. The EimAttribute structure contains information about the returned data. The API returns as much data as space has been provided. The EimAttribute structure follows:

```c
typedef struct EimAttribute
{
    unsigned int bytesReturned; /* Number of bytes actually returned by the API */
    unsigned int bytesAvailable; /* Number of bytes of available data that could have been returned by the API */
    EimListData attribute; /* handle attribute */
} EimAttribute;
```

The EimListData structure follows:

```c
typedef struct EimListData
{
    unsigned int length;        /* Length of data */
    unsigned int disp;          /* Displacement to data. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimListData;
```

**eimrc**
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

- “eimConnectToMaster” on page 214
- “eimCreateHandle” on page 223
- “eimDestroyHandle” on page 231
- “eimSetAttribute” on page 354

**Authorization**

**z/OS authorization**
No special authorization is needed.

**Return Values**
The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

</tbody>
</table>
Example
The following example gets the distinguished name (DN) of the domain for the given EIM handle:

```c
#include <eim.h>
#include <string.h>
#include <stdio.h>

int            rc;
char           eimerr[200];
EimRC        * err;
EimHandle      handle;
char         * data;
char         * listData[1000];
EimAttribute * list = (EimAttribute *) listData;
/* Set up error structure.                  */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Get EIM domain name                      */
if (0 != (rc = eimGetAttribute(&handle,
                   EIM_HANDLE_DOMAIN,
                   1000,
                   list,
                   err))) {
    char * errorString;
    if (NULL != (errorString = eimErr2String(err))) {
        printf("Get Attribute error = %d - %s\n", rc, errorString);
        free(errorString);
    } else {
        printf("Get Attribute error = %d - %s\n", rc, strerror(rc));
    }
} else {
    data = (char *)list + list->attribute.disp;
    printf("Domain name = %s\n", data);
}
```

eimGetRegistryNameFromAlias

Purpose
Returns a list of registry names that match the search criteria that aliasType and aliasValue specify.

Format
```
#include <eim.h>

int eimGetRegistryNameFromAlias(EimHandle      * eim,
                                 char           * aliasType,
                                 char           * aliasValue,
                                 unsigned int   lengthOfListData,
                                 EimList        * listData,
                                 EimRC          * eimrc)
```

Parameters

**eim**
(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.
**aliasType**
(Input) The type of alias for which to search. For a list of predefined alias types, see “EIM registry definitions and aliasing” on page 13.

**aliasValue**
(Input) The value of the alias to use for this search.

**lengthOfListData**
(Input) The number of bytes provided by the caller for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. The minimum size required is 20 bytes.

**listData**
(Output) A pointer to the data to return. The EimList structure contains information about the returned data. The data returned is a linked list of EimRegistryName structures. The firstEntry is used to get to the first EimRegistryName structure in the linked list. The number of completed EimRegistryName structures is returned in entriesReturned. The bytesReturned variable has the number of bytes the API used for the returned entries. If the number of entries returned is less than the number of entries available, the returned data contains as many complete EimRegistryName structures as will fit. It can also contain a partial EimRegistryName structure. The EimList structure follows:

```c
typedef struct EimList
{
    unsigned int bytesReturned;    /* Number of bytes actually returned by the API */
    unsigned int bytesAvailable;   /* Number of bytes of available data that could have been returned by the API */
    unsigned int entriesReturned;  /* Number of entries actually returned by the API */
    unsigned int entriesAvailable; /* Number of entries available to be returned by the API */
    unsigned int firstEntry;       /* Displacement to the first linked list entry. This byte offset is relative to the start of the EimList structure. */
} EimList;
```

The EimRegistryName structure follows:

```c
typedef struct EimRegistryName
{
    unsigned int nextEntry;        /* Displacement to next entry. This byte offset is relative to the start of this structure */
    EimListData name;              /* Name */
} EimRegistryName;
```

The EimListData structure follows:

```c
typedef struct EimListData
{
    unsigned int length;          /* Length of data */
    unsigned int disp;            /* Displacement to data. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimListData;
```

**eimrc**
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**
See the following:
Authorization

EIM data
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:
- EIM administrator
- EIM registries administrator
- EIM identifiers administrator
- EIM registry X administrator
- EIM mapping lookup

The returned list contains only the information that the user has authority to access, meaning it could be empty.

z/OS authorization
No special authorization is needed.

Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>

<tr>
<td>EUNKNOWN</td>
<td>Unexpected exception.</td>
</tr>
<tr>
<td><strong>EUNKNOWN (44)</strong></td>
<td>Unknown error or unknown system state.</td>
</tr>
</tbody>
</table>

### Example

The following example gets the registry name from the specified alias:

```c
#include <eim.h>
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>

void printListResults(EimList * list);
void printListData(char * fieldName, void * entry, int offset);

int main(int argc, char *argv[]) {
    int            rc;
    char           eimerr[200];
    EimRC        * err;
    EimHandle      handle;
    EimConnectInfo con;
    char         * ldapHost = "ldap://eimsystem:389/ibm-eimDomainName=myEimDomain,o=mycompany,c=us";
    char         * listData[1000];
    EimList      * list = (EimList * ) listData;

    /* Set up error structure. */
    memset(eimerr,0x00,200);
    err = (EimRC *)eimerr;
    err->memoryProvidedByCaller = 200;
    con.type = EIM_SIMPLE;
    con.creds.simpleCreds.protect = EIM_PROTECT_NO;
    con.creds.simpleCreds.bindDn = "cn=admin";
    con.creds.simpleCreds.bindPw = "secret";
    con.ssl = NULL;

    /* Create handle with specified LDAP URL */
    if (0 != (rc = eimCreateHandle(&handle,
                                    ldapHost,
                                    err))) {
        printf("Create handle error = %d\n", rc);
        return -1;
    }

    /* Connect with specified credentials */
    if (0 != (rc = eimConnect(&handle,
                               con,
                               err))) {
        printf("Connect error = %d\n", rc);
        eimDestroyHandle(&handle, err);
        return -1;
    }

    /* Get all aliases for the registry */
```
if (0 != (rc = eimGetRegistryNameFromAlias(&handle,
    EIM_ALIASTYPE_DNS,
    "Clueless",
    1000,
    list,
    err)))
{
    printf("List registry aliases error = %d\n", rc);
    eimDestroyHandle(&handle, err);
    return -1;
}

/* Print the results                        */
printListResults(list);
rc = eimDestroyHandle(&handle, err);
return 0;
}

void printListResults(EimList * list)
{
    int i;
    EimRegistryName * entry;

    printf("___________\n");
    printf("    bytesReturned    = %d\n", list->bytesReturned);
    printf("    bytesAvailable   = %d\n", list->bytesAvailable);
    printf("    entriesReturned  = %d\n", list->entriesReturned);
    printf("    entriesAvailable = %d\n", list->entriesAvailable);
    printf("\n");
    entry = (EimRegistryName *)((char *)list + list->firstEntry);
    for (i = 0; i < list->entriesReturned; i++)
    {
        /* Print out results */
        printListData("Registry Name",
                       entry,
                       offsetof(EimRegistryName, name));

        /* advance to next entry */
        entry = (EimRegistryName *)((char *)entry + entry->nextEntry);
    }
    printf("\n");
}

void printListData(char * fieldName, void * entry, int offset)
{
    EimListData * listData;
    char * data;
    int dataLength;

    printf("%s = ", fieldName);
    /* Address the EimListData object */
    listData = (EimListData *)((char *)entry + offset);

    /* Print out results */
    data = (char *)entry + listData->disp;
    dataLength = listData->length;
    if (dataLength > 0)
        printf("%.*s\n", dataLength, data);
    else
        printf("Not found.\n");
}

---

**Purpose**

Gets the target identity or identities for the specified registry that are associated with the specified EIM identifier.
The `eimGetTargetFromIdentifier` function is used to get information about an EIM target identity from its identifier. It takes several parameters:

- `eim`: The EIM handle that a previous call to `eimCreateHandle` returns. A valid connection is required.
- `idName`: A structure that contains the name of the identifier for this lookup operation. The layout of the `EimIdentifierInfo` structure follows:

  ```c
  enum EimIdType {
    EIM_UNIQUE_NAME,
    EIM_ENTRY_UUID,
    EIM_NAME
  };

  typedef struct EimIdentifierInfo {
    union {
      char       * uniqueName;
      char       * entryUUID;
      char       * name;
    } id;
    enum EimIdType        idtype;
  } EimIdentifierInfo;
  ```

- `idtype`: The `idtype` in the `EimIdentifierInfo` structure indicates which identifier name has been provided. `EIM_UNIQUE_NAME` and `EIM_ENTRY_UUID` find at most one matching identifier. `EIM_NAME` results in an error if your EIM domain has more than one identifier containing the same name.
- `targetRegistryName`: (Input) The target registry for this lookup operation. A null value for the string causes the service to use the system default local registry name from the instorage copy of the registry name.
- `additionalInformation`: (Input) Additional information that is selection criteria for this operation. This can be a NULL string (for example, ""). This filter data can contain the wildcard character, an asterisk (*). This field can be repeated and can contain more than one value.
- `lengthOfListData`: (Input) The number of bytes provided by the caller for the `listData` parameter. If the value of `bytesReturned` is less than `bytesAvailable` in the returned `listData` structure, you can use this number as the `bytesAvailable` size, update the `lengthOfListData` parameter, and reissue the API to retrieve the data. The minimum size required is 20 bytes.
- `listData`: (Output) A pointer to the data to return. The `EimList` structure contains information about the returned data. The data returned is a linked list of `EimTargetIdentity` structures. The `firstEntry` is used to get to the first `EimTargetIdentity` structure in the linked list. The number of completed `EimTargetIdentity` structures is returned in `entriesReturned`. The `bytesReturned` variable has the number of bytes the API used for the returned entries. If the number of entries returned is less than the number of entries
available, the returned data contains as many complete EimTargetIdentity structures as will fit. It can also contain a partial EimTargetIdentity structure. The EimList structure follows:

```c
typedef struct EimList
{
    unsigned int bytesReturned;  /* Number of bytes actually returned by the API. */
    unsigned int bytesAvailable; /* Number of bytes of available data that could have been returned by the API. */
    unsigned int entriesReturned; /* Number of entries actually returned by the API. */
    unsigned int entriesAvailable; /* Number of entries available to be returned by the API. */
    unsigned int firstEntry;      /* Displacement to the first linked list entry. This byte offset is relative to the start of the EimList structure. */
} EimList;
```

The EimTargetIdentity structure follows:

```c
typedef struct EimTargetIdentity
{
    unsigned int nextEntry;      /* Displacement to next entry. This byte offset is relative to the start of this structure. */
    EimListData userName;        /* User name */
} EimTargetIdentity;
```

The EimListData structure follows:

```c
typedef struct EimListData
{
    unsigned int length;          /* Length of data */
    unsigned int disp;            /* Displacement to data. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimListData;
```

eimrc

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information

See the following:

- “eimGetTargetFromSource” on page 262

Authorization

EIM data

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM registries administrator
- EIM identifiers administrator
- EIM registry X administrator
- EIM mapping-lookup

The list returned contains only the information that the user has authority to access.

z/OS authorization

The calling application can be running in system key or supervisor state or one of the following:
• The RACF user ID of the caller’s address space has READ authority to the BPX.SERVER profile in the FACILITY class
• The current RACF user ID has READ authority to the IRR.RGETINFO.EIM profile in the FACILITY class

The FACILITY class must be active and RACLISTed before unauthorized (problem program state and keys) will be granted the authority to use this SAF service.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>

<tr>
<td></td>
<td>EIMERR_ZOS_DATA_CONVERSION (6011)</td>
</tr>
<tr>
<td></td>
<td>Error occurred when converting data between code pages.</td>
</tr>
</tbody>
</table>
Return Value | Meaning
--- | ---
ENOMEM | Unable to allocate required space.
**EIMERR_NOMEM** (27) | No memory available. Unable to allocate required space.
ENOSYS | EIM is not configured
**EIMERR_NOTCONFIG** (30) | (Only z/OS returns this value.) EIM environment is not configured. On z/OS, issue RACF commands to correct the configuration error and then try the request again.
ENOTCONN | LDAP connection has not been made.
**EIMERR_NOT_CONN** (31) | Not connected to LDAP. Use the eimConnect API or the eimConnectToMaster API and try the request again.
EUNKNOWN | Unexpected exception.
**EIMERR_LDAP_ERR** (23) | Unexpected LDAP error.
**EIMERR_UNEXP_OBJ_VIOLATION** (56) | Unexpected object violation.
**EIMERR_UNKNOWN** (44) | Unknown error or unknown system state.

Example
The following example gets the list of users in the target registry, MyRegistry, that is associated with the specified identifier:

```c
#include <eim.h>
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>

void printListResults(EimList * list);
void printListData(char * fieldName, void * entry, int offset);

int main(int argc, char *argv[])
{
    int               rc;
    char              eimerr[200];
    EimRC           * err;
    EimHandle         handle;
    EimConnectInfo    con;
    char            * ldapHost = "ldap://eimsystem:389/ibm-eimDomainName=myEimDomain,o=mycompany,c=us";
    char              listData[4000];
    EimList         * list = (EimList * ) listData;
    EimIdentifierInfo x;

    /* Set up error structure. */
    Memset(eimerr, 0x00, 200);
    err = (EimRC *)eimerr;
    err->memoryProvidedByCaller = 200;

    con.type = EIM_SIMPLE;
    con.creds.simpleCreds.protect = EIM_PROTECT_NO;
    con.creds.simpleCreds.bindDn = "cn=admin";
    con.creds.simpleCreds.bindPw = "secret";
    con.ssl = NULL;

    /* Create handle with specified LDAP URL */
    if (0 != (rc = eimCreateHandle(&handle,
                                  ldapHost,
                                  err)))
        printf("Create handle error = %d\n", rc);

    printListResults(list);
}
```
return -1;
}

/* Connect with specified credentials */
if (0 != (rc = eimConnect(&handle, con, err))) {
    printf("Connect error = %d\n", rc);
eimDestroyHandle(&handle, err);
return -1;
}

/* Set up identifier information */
x.idtype = EIM_UNIQUE_NAME;
x.id.uniqueName = "mjones";

if (0 != (rc = eimGetTargetFromIdentifier(&handle, &x, "MyRegistry", NULL, 4000, list, err)))
{
    printf("Get Target from identifier error = %d\n", rc);
eimDestroyHandle(&handle, err);
return -1;
}
printListResults(list);

/* Destroy the handle */
rc = eimDestroyHandle(&handle, err);
return 0;
}

void printListResults(EimList * list)
{
    int i;
    EimTargetIdentity * entry;

    printf("___________\n");
    printf(" bytesReturned   = %d\n", list->bytesReturned);
    printf(" bytesAvailable = %d\n", list->bytesAvailable);
    printf(" entriesReturned = %d\n", list->entriesReturned);
    printf(" entriesAvailable = %d\n", list->entriesAvailable);
    printf("\n");

    entry = (EimTargetIdentity*)(char*)list + list->firstEntry;
    for (i = 0; i < list->entriesReturned; i++)
    {
        printf("\n");
        printf("\n");
        printf("Entry %d.\n", i);
        /* Print out results */
        printListData("target user", entry,
        offsetof(EimTargetIdentity, userName));
        /* advance to next entry */
        entry = (EimTargetIdentity*)(char*)entry + entry->nextEntry;
    }
    printf("\n");
}

void printListData(char * fieldName, void * entry, int offset)
{
    EimListData * listData;
    char * data;
    int dataLength;

    printf("    %s = ", fieldName);
    /* Address the EimListData object */
    listData = (EimListData*)((char*)entry + offset);
    /* Print out results */
    data = (char*)entry + listData->disp;
dataLength = listData->length;

```c
if (dataLength > 0)
    printf("%.*s\n",dataLength, data);
else
    printf("Not found.\n");
}
```

---

**eimGetTargetFromSource**

**Purpose**

Gets the target identity or identities associated with the source identity (as defined by source registry name and source registry user). This is known as a mapping lookup operation -- from the known source information this API returns the user for this target registry.

The mapping lookup operation is done in the following order:

1. Check if both the source and target registries support mapping lookup operations. If not, no data is returned.
2. Specific source association to target association:
   - Check for source associations to EIM identifier(s) using the specified source registry user name and source registry. If none is found, proceeds to step 3.
   - Check for target associations to the EIM identifier(s) using the specified target registry. If none are found, proceeds to step 3.
   - If additional information is specified, check if any of the target identities have the same additional information. If not, proceeds to step 3.
   - Return the target identity(ies) for the specified target registry that have the same additional information that is specified.
3. Check if the domain supports policy associations. If not, no data is returned.
4. Check if the target registry supports policy associations. If not, no data is returned.
5. Certificate filter policy associations:
   - Check if the source registry is an X.509 registry. If not, proceeds to step 6.
   - Check if there is a certificate policy filter value that matches the source identity. If not, proceeds to step 6.
   - Check for certificate filter policy associations for the certificate filter policy value to the target registry. If none are found, proceeds to step 6.
   - If additional information is specified, check if any of the target identities have the same additional information. If not, proceeds to step 6.
   - Return the target identity(ies) for the specified target registry that have the same additional information that is specified.
6. Default registry policy associations:
   - Check for default registry policy associations for the source registry to the target registry. If none are found, proceeds to step 7.
   - If additional information is specified, check if any of the target identities have the same additional information. If not, proceeds to step 7.
   - Return the target identity(ies) for the specified target registry that have the same additional information that is specified.
7. Default domain policy associations:
   - Check for default domain policy associations to the target registry. If none are found, no data is returned.
If additional information is specified, check if any of the target identities have the same additional information. If not, no data is returned.

Return the target identity(ies) for the specified target registry that have the same additional information that is specified.

Format

```c
#include <eim.h>

int eimGetTargetFromSource(EimHandle *eim,
                           char *sourceRegistryName,
                           char *sourceRegistryUserName,
                           char *targetRegistryName,
                           char *additionalInformation,
                           unsigned int lengthOfListData,
                           EimList *listData,
                           EimRC *eimrc)
```

Parameters

eim
(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

sourceRegistryName
(Input) The source registry for this lookup operation. A null value for the string causes the service to use the system default local registry name from the instorage copy of the registry name.

sourceRegistryUserName
(Input) The source user name for this lookup operation. The registry user name should begin with a non-blank character.

targetRegistryName
(Input) The target registry for this lookup operation. A null value for the string causes the service to use the system default local registry name from the instorage copy of the registry name.

additionalInfo
(Input) Additional information to use as selection criteria for this operation. This can be NULL. This filter data can contain the wild card character, an asterisk (*).

lengthOfListData
(Input) The number of bytes provided by the caller for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. The minimum size required is 20 bytes.

listData
(Output) A pointer to the data to return. The EimList structure contains information about the returned data. Entries are returned when the user is a member of the required EIM access group and the source and target registries exist. When the user is not a member of the required EIM access group or the target registry does not exist, the return value is zero and no entries are returned. The EimList structure follows:

```c
typedef struct EimList {
    unsigned int bytesReturned;    /* Number of bytes actually returned by the API */
    unsigned int bytesAvailable;   /* Number of bytes of available data that could be returned by the API */
    unsigned int entriesReturned;  /* Number of entries actually returned by the API */
    unsigned int entriesAvailable; /* Number of entries available to be returned by the API */
    unsigned int firstEntry;       /* Displacement to the first linked list entry. This byte offset is relative to the start of the... */
} EimList;
```
The EimTargetIdentity structure follows:

```c
typedef struct EimTargetIdentity {
    unsigned int nextEntry; /* Displacement to next entry. This byte offset is relative to the start of this structure */
    EimListData userName; /* User name */
} EimTargetIdentity;
```

The EimListData structure follows:

```c
typedef struct EimListData {
    unsigned int length; /* Length of data */
    unsigned int disp; /* Displacement to data. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimListData;
```

**eimrc**

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

### Related Information

See the following:

- “eimGetTargetFromIdentifier” on page 256

### Authorization

#### EIM data

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM registries administrator
- EIM identifiers administrator
- EIM mapping-lookup administrator
- EIM registry $X$ administrator (for the source and target registries)

The list returned contains only the information that the user has authority to access.

#### z/OS authorization

The calling application can be running in system key or supervisor state or one of the following:

- The RACF user ID of the caller’s address space has READ authority to the BPX.SERVER profile in the FACILITY class
- The current RACF user ID has READ authority to the IRR.RGETINFO.EIM profile in the FACILITY class

The FACILITY class must be active and RA CLIsted before unauthorized (problem program state and keys) will be granted the authority to use this SAF service.

### Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.
<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful. If a target user ID is not returned in the listData and associations are defined between the source registry user ID and the target registry, ensure the user specified on the eimConnect or eimConnectToMaster is a member of the required EIM access group.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>
</tr>
<tr>
<td>EBADDATA</td>
<td>eimrc is not valid.</td>
</tr>
<tr>
<td>EBADNAME</td>
<td>Source registry not found or insufficient access to EIM data. <strong>EIMERR_NOREG (28)</strong> EIM registry not found or the bind user specified on the EIM connect API is only a member of the target registry's EIM registry X administrator access group. If a target user ID is not returned in the listData and associations are defined between the source registry user ID and the target registry, ensure the user specified on the eimConnect or eimConnectToMaster is a member of the required EIM access group.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>Unable to allocate internal system object. <strong>EIMERR_NOLOCK (26)</strong> (z/OS does not return this value.) Unable to allocate internal system object.</td>
</tr>
<tr>
<td>ECONVERT</td>
<td>Data conversion error. <strong>EIMERR_DATA_CONVERSION (13)</strong> (z/OS does not return this value.) Error occurred when converting data between code pages.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Input parameter was not valid. <strong>EIMERR_EIMLIST_SIZE (16)</strong> Length of EimList is not valid. EimList must be at least 20 bytes in length. <strong>EIMERR_HANDLE_INVAL (17)</strong> EimHandle is not valid. <strong>EIMERR_PARM_REQ (34)</strong> Missing required parameter. Please check the API documentation. <strong>EIMERR_PTR_INVAL (35)</strong> (z/OS does not return this value.) Pointer parameter is not valid. <strong>EIMERR_SPACE (41)</strong> Unexpected error accessing parameter.</td>
</tr>
<tr>
<td>EMVSERR</td>
<td>An MVS environment or internal error has occurred. <strong>EIMERR_ZOS_DATA_CONVERSION (6011)</strong> Error occurred when converting data between code pages.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Unable to allocate required space. <strong>EIMERR_NOMEM (27)</strong> No memory available. Unable to allocate required space.</td>
</tr>
<tr>
<td>ENOSYS</td>
<td>EIM is not configured <strong>EIMERR_NOTCONFIG (30)</strong> (Only z/OS returns this value.) EIM environment is not configured. On z/OS, issue RACF commands to correct the configuration error and then try the request again.</td>
</tr>
<tr>
<td>Return Value</td>
<td>Meaning</td>
</tr>
<tr>
<td>--------------</td>
<td>---------</td>
</tr>
<tr>
<td>ENOTCONN</td>
<td>LDAP connection has not been made.</td>
</tr>
<tr>
<td>EIMERR_NOT_CONN (31)</td>
<td>Not connected to LDAP. Use the eimConnect API or eimConnectToMaster API and try the request again.</td>
</tr>
<tr>
<td>EUNKNOWN</td>
<td>Unexpected exception.</td>
</tr>
<tr>
<td>EIMERR_LDAP_ERR (23)</td>
<td>Unexpected LDAP error.</td>
</tr>
<tr>
<td>EIMERR_UNEXP_OBJ_VIOLATION (56)</td>
<td>Unexpected object violation.</td>
</tr>
<tr>
<td>EIMERR_UNKNOWN (44)</td>
<td>Unknown error or unknown system state.</td>
</tr>
</tbody>
</table>

**Example**

The following example gets the target identity that is associated with the source information:

```c
#include <eim.h>
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>

void printListResults(EimList * list);
void printListData(char * fieldName, void * entry, int offset);

int main(int argc, char *argv[]) {
    int           rc;
    char          eimerr[200];
    EimRC         * err;
    EimHandle     handle;
    EimConnectInfo con;
    char          * ldapHost = "ldap://eimsystem:389/ibm-eimDomainName=myEimDomain,o=mycompany,c=us";
    char          listData[4000];
    EimList       * list = (EimList * ) listData;

    /* Set up error structure. */
    Memset(eimerr, 0x00, 200);
    err = (EimRC *)eimerr;
    err->memoryProvidedByCaller = 200;

    con.type = EIM_SIMPLE;
    con.creds.simpleCreds.protect = EIM_PROTECT_NO;
    con.creds.simpleCreds.bindDn = "cn=admin";
    con.creds.simpleCreds.bindPw = "secret";
    con.ssl = NULL;

    /* Create handle with specified LDAP URL */
    if (0 != (rc = eimCreateHandle(&handle, ldapHost, err))) {
        printf("Create handle error = %d\n", rc);
        return -1;
    }

    /* Connect with specified credentials */
    if (0 != (rc = eimConnect(&handle, con, err))) {
        printf("Connect error = %d\n", rc);
        eimDestroyHandle(&handle, err);
        return -1;
    }

    break;

default:
    printf("ERROR - unknown association type.\n");
    break;

}
}

---

**eimGetVersion**

**Purpose**

Returns the EIM version supported by the APIs for the specified host.

**Format**

```c
#include <eim.h>
int eimGetVersion(EimHostInfo * hostInfo,
                    enum EimVersion * version,
                    EimRC * eimrc)
```

**Parameters**

- **eim**
  (Input) The EIM handle returned by a previous call to `eimCreateHandle`. A valid connection is required for this function.

- **hostInfo**
  (Input) The structure that contains the EIM host information for which to return the EIM version supported by the EIM APIs.

  For **EIM_HANDLE (0) host type**, this field must contain an EIM handle returned by a previous call to `eimCreateHandle` and `eimConnect`.

  For **EIM_LDAP_URL (1) host type**, this field must contain a uniform resource locator (URL) that contains the EIM host information. A NULL value for the ldapURL field indicates that the ldap URL information set by the `eimSetConfiguration` API should be used. This URL has the following format:

  ```
  ldap://host:port/dn
  ```

  or

  ```
  ldaps://host:port
  ```

  Where:

  - **host:port**
    The name of the host on which the EIM domain controller is running with an optional port number.

  - **dn**
    The distinguished name of the domain to work with (optional).

  - **ldaps**
    Indicates that this host/port combination uses SSL and TLS.

  The structure layout follows:

  ```
  enum EimHostInfoType {
    EIM_HANDLE, 
    EIM_LDAP_URL
  };
  typedef struct EimHostInfo {
  ```
**version**
(Output) The EIM version supported by the EIM APIs for the specified host. Possible values are:

**EIM_VERSION_0 (0)**
EIM is not supported on the specified host.

**EIM_VERSION_1 (1)**
EIM version 1 is supported by the EIM APIs for the specified host. This host will support EIM functionality provided with the first version of the EIM APIs.

**EIM_VERSION_2 (2)**
EIM version 2 is supported by the EIM APIs for the specified host. This host will support EIM functionality provided with the second version of the EIM APIs, which includes support for policy associations.

**eimrc**
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see "EimRC -- EIM return code parameter for C/C++" on page 166.

**Related Information**
None.

**Authorization**

**EIM data**
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator

**z/OS authorization**
No special authorization is needed.

**Return Values**
The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>

</tbody>
</table>
### eimListAccess

**Purpose**
Lists the users that have the specified EIM access type.

**Format**

```c
#include <eim.h>

int eimListAccess(EimHandle *eim, 
enum EimAccessType accessType, 
char *registryName, 
unsigned int lengthOfListData, 
EimList *listData, 
EimRC *eimrc)
```

**Parameters**

- **eim**  
  (Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

- **accessType**  
  (Input) The type of access to list. Valid values are:

  - **EIM_ACCESS_ADMIN (0)**  
    Administrative authority to the entire EIM domain.

  - **EIM_ACCESS_REG_ADMIN (1)**  
    Administrative authority to all registries in the EIM domain.

  - **EIM_ACCESS_REGISTRY (2)**  
    Administrative authority to the registry specified in the `registryName` parameter.

  - **EIM_ACCESS_IDENTIFIER_ADMIN (3)**  
    Administrative authority to all of the identifiers in the EIM domain.

  - **EIM_ACCESS_MAPPING_LOOKUP (4)**  
    Authority to perform mapping lookup operations.

- **registryName**  
  (Input) The name of the EIM registry for which to list access. Registry names are case-independent (meaning, not case-sensitive). If `eimAccessType` is anything other than EIM_ACCESS_REGISTRY, this parameter must be null.

  The following special characters are not allowed in registry names:

  `\ , = + < > # ; \ *`

### Return Value

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>EUNKNOWN</td>
<td>Unexpected exception.</td>
</tr>
<tr>
<td>EIMERR_LDAP_ERR (23)</td>

</tr>
<tr>
<td>EIMERR_UNKNOWN (44)</td>
<td>Unknown error or unknown system state.</td>
</tr>
<tr>
<td>EIMERR_LDAP_SCHEMA_NOT_FOUND (71)</td>
<td>Unable to find LDAP schema.</td>
</tr>
</tbody>
</table>

---

**EIM APIs 271**
lengthOfListData
(Input) The number of bytes the caller provides for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. The minimum size required is 20 bytes.

listData
(Output) A pointer to the data to return.

The EimList structure contains information about the returned data. The data returned is a linked list of EimAccess structures. The firstEntry is used to get to the first EimAccess structures in the linked list. The number of completed EimAccess structures is returned in entriesReturned. The bytesReturned variable has the number of bytes the API used for the returned entries. If the number of entries returned is less than the number of entries available, the returned data contains as many complete EimAccess structures as will fit. It can also contain a partial EimAccess structures.

The EimList structure follows:

```c
typedef struct EimList {
    unsigned int bytesReturned; /* Number of bytes actually returned by the API */
    unsigned int bytesAvailable; /* Number of bytes of available data that could have been returned by the API */
    unsigned int entriesReturned; /* Number of entries actually returned by the API */
    unsigned int entriesAvailable; /* Number of entries available to be returned by the API */
    unsigned int firstEntry; /* Displacement to the first linked list entry. This byte offset is relative to the start of the EimList structure. */
} EimList;
```

The EimAccess structure follows:

```c
typedef struct EimAccess {
    unsigned int nextEntry; /* Displacement to next entry. This byte offset is relative to the start of this structure */
    EimListData user; /* User with access. This data will be in the format of the DN for access id. */
} EimAccess;
```

The EimListData structure follows:

```c
typedef struct EimListData {
    unsigned int length; /* Length of data */
    unsigned int disp; /* Displacement to data. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimListData;
```

eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information

See the following:
- “eimAddAccess” on page 167
- “eimListUserAccess” on page 321
Authorization

EIM data
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator

The list returned contains only the information that the user has authority to access.

z/OS authorization
No special authorization is needed.

Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCESS</td>
<td>Access denied. Not enough permissions to access data.</td>
</tr>
<tr>

        printf("%.*s\n",dataLength, data);
    else
        printf("Not found.\n");

eimListAssociations

Purpose
Returns a list of associations for a given EIM identifier. You can use this to find all of the associated identities for an individual in the enterprise. Note that this does not return policy associations.

Format
#include <eim.h>
Parameters

eim
(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

associationType
(Input) The type of association to list. Valid values are:

EIM_ALL_ASSOC (0)
List all associations.

EIM_TARGET (1)
List target associations.

EIM_SOURCE (2)
List source associations.

EIM_SOURCE_AND_TARGET (3)
List both source and target associations.

EIM_ADMIN (4)
List administrative associations.

idName
(Input) A structure that contains the identifier name indicating the associations to list. The layout of the EimIdentifierInfo structure follows:

```c
enum EimIdType {
    EIM_UNIQUE_NAME,
    EIM_ENTRY_UUID,
    EIM_NAME
};

typedef struct EimIdentifierInfo
{
    union {
        char       * uniqueName;
        char       * entryUUID;
        char       * name;
    } id;
    enum EimIdType        idtype;
} EimIdentifierInfo;
```

idtype
The idtype in the EimIdentifierInfo structure indicates which identifier name has been provided. EIM_UNIQUE_NAME finds at most one matching identifier. EIM_NAME results in an error if your EIM domain has more than one identifier containing the same name.

lengthOfListData
(Input) The number of bytes the caller provides for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. Minimum size required is 20 bytes.

listData
(Output) A pointer to the EimList structure.

The EimList structure contains information about the returned data. The data returned is a linked list of EimAssociation structures. The firstEntry field in the EimList structure is used to get to the first EimAssociation structure in the linked list. The number of completed EimAssociation structures is returned in entriesReturned. The bytesReturned variable has the number of bytes the API used for the
returned entries. If the number of entries returned is less than the number of entries available, the returned data contains as many complete EimAssociation structures as will fit. It can also contain a partial EimAssociation structure. The EimList structure follows:

```c
typedef struct EimList
{
    unsigned int bytesReturned;  /* Number of bytes actually returned
                                 by the API */
    unsigned int bytesAvailable; /* Number of bytes of available data
                                 that could have been returned by
                                 the API */
    unsigned int entriesReturned; /* Number of entries actually
                                 returned by the API */
    unsigned int entriesAvailable; /* Number of entries available to be
                                 returned by the API */
    unsigned int firstEntry;     /* Displacement to the first linked
                                 list entry. This byte offset is
                                 relative to the start of the
                                 EimList structure. */
} EimList;
```

The EimAssociation structure follows:

```c
typedef struct EimAssociation
{
    unsigned int nextEntry;     /* Displacement to next entry. This byte offset is relative to the start of this structure */
    enum EimAssociationType associationType; /* Type of association */
    EimListData registryType;    /* Registry type */
    EimListData registryName;    /* Registry name */
    EimListData registryUserName; /* Registry user name */
} EimAssociation;
```

The EimListData structure follows:

```c
typedef struct EimListData
{
    unsigned int length;       /* Length of data */
    unsigned int disp;         /* Displacement to data. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimListData;
```

eimrc

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information

See the following:

- “eimAddAssociation” on page 174
- “eimGetAssociatedIdentifiers” on page 243
- “eimRemoveAssociation” on page 333

Authorization

**EIM data**

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM registries administrator
- EIM identifiers administrator
EIM registry X administrator
EIM mapping lookup

The list returned contains only the information that the user has authority to access.

**z/OS authorization**
No special authorization is needed.

## Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the `messageCatalogMessageID` field in the `eimrc` parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>

<tr>
<td>EBADDATA</td>
<td><code>eimrc</code> is not valid.</td>
</tr>
<tr>
<td>EBADNAME</td>
<td>Identifier name is not valid.</td>
</tr>
<tr>
<td><strong>EIMERR_IDNAME_AMBIGUOUS (20)</strong></td>
<td>More than one EIM identifier was found that matches the requested identifier name.</td>
</tr>
<tr>
<td><strong>EIMERR_NOIDENTIFIER (25)</strong></td>
<td>EIM identifier not found or insufficient access to EIM data.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>Unable to allocate internal system object.</td>
</tr>
<tr>
<td><strong>EIMERR_NOLOCK (26)</strong></td>
<td>(z/OS does not return this value.) Unable to allocate internal system object.</td>
</tr>
<tr>
<td>ECONVERT</td>
<td>Data conversion error.</td>
</tr>
<tr>
<td><strong>EIMERR_DATA_CONVERSION (13)</strong></td>
<td>(z/OS does not return this value.) Error occurred when converting data between code pages.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Input parameter was not valid.</td>
</tr>
<tr>
<td><strong>EIMERR_ASSOC_TYPE_INVAL (4)</strong></td>
<td>Association type is not valid.</td>
</tr>
<tr>
<td><strong>EIMERR_EIMLIST_SIZE (16)</strong></td>
<td>Length of EimList is not valid. EimList must be at least 20 bytes in length.</td>
</tr>
<tr>
<td><strong>EIMERR_HANDLE_INVAL (17)</strong></td>
<td>EimHandle is not valid.</td>
</tr>
<tr>
<td><strong>EIMERR_IDNAME_TYPE_INVAL (52)</strong></td>
<td>The EimIdType value is not valid.</td>
</tr>
<tr>
<td><strong>EIMERR_PARM_REQ (34)</strong></td>
<td>Missing required parameter. Please check the API documentation.</td>
</tr>
<tr>
<td><strong>EIMERR_PTR_INVAL (35)</strong></td>
<td>(z/OS does not return this value.) Pointer parameter is not valid.</td>
</tr>
<tr>
<td><strong>EIMERR_SPACE (41)</strong></td>
<td>Unexpected error accessing parameter.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Unable to allocate required space.</td>
</tr>
<tr>
<td><strong>EIMERR_NOMEM (27)</strong></td>
<td>No memory available. Unable to allocate required space.</td>

<td>Return Value</td>
<td>Meaning</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ENOTCONN</td>
<td>LDAP connection has not been made.</td>
</tr>
<tr>
<td>EIMERR_NOT_CONN (31)</td>
<td>Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.</td>
</tr>
<tr>
<td>EUNKNOWN</td>
<td>Unexpected exception.</td>
</tr>
<tr>
<td>EIMERR_LDAP_ERR (23)</td>
<td>Unexpected LDAP error.</td>
</tr>
<tr>
<td>EIMERR_UNEXP_OBJ_VIOLATION (56)</td>
<td>Unexpected object violation.</td>
</tr>
<tr>
<td>EIMERR_UNKNOWN (44)</td>
<td>Unknown error or unknown system state.</td>
</tr>
</tbody>
</table>

**Example**

The following example lists the associations for an identifier:

```c
#include <eim.h>
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>

void printListResults(EimList * list);
void printAssociationType(int type);
void printListData(char * fieldName, void * entry, int offset);

int main(int argc, char *argv[])
{
    int               rc;
    char              eimerr[200];
    EimRC           * err;
    EimHandle         handle;
    EimConnectInfo    con;
    char            * ldapHost =
        "ldap://eimsystem:389/ibm-eimDomainName=myEimDomain,o=mycompany,c=us";
    char              listData[4000];
    EimList         * list = (EimList * ) listData;
    EimIdentifierInfo x;

    /* Set up error structure. */
    Memset(eimerr, 0x00, 200);
    err = (EimRC *)eimerr;
    err->memoryProvidedByCaller = 200;
    con.type = EIM_SIMPLE;
    con.creds.simpleCreds.protect = EIM_PROTECT_NO;
    con.creds.simpleCreds.bindDn = "cn=admin";
    con.creds.simpleCreds.bindPw = "secret";
    con.ssl = NULL;

    /* Create handle with specified LDAP URL */
    if (0 != (rc = eimCreateHandle(&handle,
        ldapHost, err))) {
        printf("Create handle error = %d\n", rc);
        return -1;
    }

    /* Connect with specified credentials */
    if (0 != (rc = eimConnect(&handle,
        con, err))) {
        printf("Connect error = %d\n", rc);
        eimDestroyHandle(&handle, err);
        return -1;
    }

    /* Set up identifier information */
    x.idtype = EIM_UNIQUE_NAME;
```
x.id.uniqueName = "mjones";

/* Get associations for this identifier */

        printf("ERROR - unknown association type.\n"); break;
    }
void printListData(char * fieldName, void * entry, int offset)
{
    EimListData * listData;
    char * data;
    int dataLength;

    printf("%s = ", fieldName);
    /* Address the EimListData object */
    listData = (EimListData *)((char *)entry + offset);

    /* Print out results */
    data = (char *)entry + listData->disp;
    dataLength = listData->length;
    if (dataLength > 0)
        printf("%.*s\n", dataLength, data);
    else
        printf("Not found.\n");
}

---

eimListDomains

**Purpose**

Lists information for a single EIM domain or for all EIM domains that are stored on an LDAP server. To list a single domain, the `ldapURL` parameter must contain the distinguished name of the EIM domain.

To list all domains stored on an LDAP server, omit the distinguished name of the EIM domain from the `ldapURL` parameter.

**Format**

```c
#include <eim.h>

int eimListDomains(char * ldapURL,
                    EimConnectInfo connectInfo,
                    unsigned int lengthOfListData,
                    EimList * listData,
                    EimRC * eimrc)
```

**Parameters**

**ldapURL**

(Input) A uniform resource locator (URL) that contains the EIM host information. This parameter is required. This URL has the following format:

- `ldap://host:port/dn`
- `ldaps://host:port/dn`

**host:port**

Name of the host on which the EIM domain controller is running. (The port number is optional. If not specified, the default LDAP or LDAPS port will be used.)

**dn**

Distinguished name of the domain to list. If you do not specify DN, then eimListDomains returns all domains stored on an LDAP server.
Example:
ldap://systemx:389/ibm-eimDomainName=myEimDomain,o=myCompany,c=us
ldaps://systemy:636/ibm-eimDomainName=thisEimDomain,o=myCompany,c=us

Note: In contrast with ldap, ldaps indicates that this host and port combination uses SSL and TLS.

connectInfo
(Input) Connect information. This parameter provides the information required to bind to LDAP. If the system is configured to connect to a secure port, EimSSLInfo is required.

For the EIM_SIMPLE connect type, the creds field should contain the EimSimpleConnectInfo structure with a binddn and password.

EimPasswordProtect determines the level of password protection on the LDAP bind.

EIM_PROTECT_NO (0)
The clear-text password is sent on the bind.

EIM_PROTECT_CRAM_MD5 (1)
The protected password is sent on the bind. The server side must support cram-md5 protocol to send the protected password.

EIM_PROTECT_CRAM_MD5_OPTIONAL (2)
The protected password is sent on the bind if the cram-md5 protocol is supported. Otherwise, the clear-text password is sent.

For EIM_KERBEROS, the default logon credentials are used. The kerberos_creds field must be NULL.

For EIM_CLIENT_AUTHENTICATION, the creds field is ignored. The ssl field must point to a valid EimSSLInfo structure. The keyring field is required in the EimSSLInfo structure. It can be the name of a System SSL key database file or a RACF keyring name. The keyring_pw field is required when the keyring is the name of a System SSL key database field. The certificateLabel field is optional. If it is NULL the default certificate in the keyring is used.

The structure layouts follow:

```c
enum EimPasswordProtect {
    EIM_PROTECT_NO,
    EIM_PROTECT_CRAM_MD5,
    EIM_PROTECT_CRAM_MD5_OPTIONAL
};
enum EimConnectType {
    EIM_SIMPLE,
    EIM_KERBEROS,
    EIM_CLIENT_AUTHENTICATION
};
typedef struct EimSimpleConnectInfo {
    enum EimPasswordProtect protect;
    char * bindDn;
    char * bindPw;
} EimSimpleConnectInfo;
typedef struct EimSSLInfo {
    char * keyring;
    char * keyring_pw;
    char * certificateLabel;
} EimSSLInfo;
typedef struct EimConnectInfo {
    enum EimConnectType type;
    union {
        gss_cred_id_t * kerberos;
        EimSimpleConnectInfo simpleCreds;
    }
};
```
lengthOfListData
(Input) The number of bytes the caller provides for the list of domains. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. The API returns the number of bytes available for the entire list and as much data as space has been provided. Minimum size required is 20 bytes.

listData
(Output) A pointer to the data to return. The EimList structure contains information about the returned data. The data returned is a linked list of EimDomain structures. The firstEntry field in the EimList Structure is used to get to the first EimDomain structure in the linked list. The number of completed EimDomain structures is returned in entriesReturned. The bytesReturned variable has the number of bytes the API used for the returned entries. If the number of entries returned is less than the number of entries available, the returned data contains as many complete EimDomain structures as will fit. It can also contain a partial EimDomain structure. The EimList structure follows:

typedef struct EimList
{
    unsigned int bytesReturned;     /* Number of bytes actually returned
        by the API */
    unsigned int bytesAvailable;    /* Number of bytes of available data
        that could have been returned by
        the API */
    unsigned int entriesReturned;   /* Number of entries actually
        returned by the API */
    unsigned int entriesAvailable;  /* Number of entries available to be
        returned by the API */
    unsigned int firstEntry;        /* Displacement to the first linked
        list entry. This byte offset is
        relative to the start of the
        EimList structure. */
} EimList;

The EimDomain structure follows:

typedef struct EimDomain
{
    unsigned int nextEntry;         /* Displacement to next entry. This
        byte offset is relative to the
        start of this structure */
    EimListData name;               /* Domain name */
    EimListData DN;                 /* Distinguished name for the domain */
    EimListData description;        /* Description */
    enum EimStatus policyAssociations;  /* Policy associations attribute */
} EimDomain;

The EimListData structure follows:

typedef struct EimListData
{
    unsigned int length;            /* Length of data */
    unsigned int disp;              /* Displacement to data. This byte
        offset is relative to the start of
        the structure containing this
        structure. */
} EimListData;

eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.
Related Information

See the following:

- “eimChangeDomain” on page 191
- “eimCreateDomain” on page 219
- “eimDeleteDomain” on page 227

Authorization

EIM data

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator

The list returned contains only the information that the user has authority to access.

z/OS authorization

No special authorization is needed.

Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>

### Example

The following example lists the information for the specified EIM domain:

```c
#include <eim.h>
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

void printListResults(EimList * list);
void printListData(char * fieldName, void * entry, int offset);

int main(int argc, char *argv[]) {

    eimListDomains
```

---

**EIM APIs 285**
int rc;
char eimerr[200];
EimRC * err;
char listData[1000];
EimList * list = (EimList *) listData;
char * errstr;

char * ldapURL = "ldap://localhost:389";

EimConnectInfo con;

/* Set up connection information */
con.type = EIM_SIMPLE;
con.creds.simpleCreds.protect = EIM_PROTECT_NO;
con.creds.simpleCreds.bindDn = "cn=administrator";
con.creds.simpleCreds.bindPw = "secret";
con.ssl = NULL;

/* Set up error structure. */
memset(eimerr, 0x00, 200);
err = (EimRC *) eimerr;
err->memoryProvidedByCaller = 200;

/* Get info for specified domain */
if (0 != (rc = eimListDomains(ldapURL,
con, 1000, list, err)))
{
    printf("List domain error = %d - %s\n", rc, errstr = eimErr2String(err));
    if (NULL != errstr) free(errstr);
    return -1;
}

/* Print the results */
printListResults(list);
return 0;

}

void printListResults(EimList * list)
{
    int i;
    EimDomain * entry;

printListData("description",
entry,
offsetof(EimDomain, description));
printf("  Policy Associations are ");

        status = (enum EimStatus *)((char *) entry +
offsetof(EimDomain, policyAssociations));
        if (*status == EIM_STATUS_ENABLED) {
            printf("Enabled\n");
        } else {
            printf("Disabled\n");
    }
eimListIdentifiers

**Purpose**

Returns a list of identifiers in the EIM domain. idName can be used to filter the results returned.

**Format**

```c
#include <eim.h>

int eimListIdentifiers(EimHandle         * eim,
                        EimIdentifierInfo * idName,
                        unsigned int       lengthOfListData,
                        EimList           * listData,
                        EimRC             * eimrc)
```

**Parameters**

- **eim**
  - (Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

- **idName**
  - (Input) A structure that contains the name for this identifier. This parameter can be NULL; in this case the API returns all identifiers in the domain. The layout of the EimIdentifierInfo structure follows:

```c
enum EimIdType {
    EIM_UNIQUE_NAME,
    EIM_ENTRY_UUID,
    EIM_NAME
};

typedef struct EimIdentifierInfo {
    union {
        char       * uniqueName;
        char       * entryUUID;
        char       * name;
    }

    union {
        char       * uniqueName;
        char       * entryUUID;
        char       * name;
    }

    // Other fields...
};
```

- **lengthOfListData**
  - (Input) The length of the list of identifiers.

- **listData**
  - (Output) A list of identifiers.

- **eimrc**
  - (Output) An EimRC structure that holds the return status of the API call.
idtype
The idtype in the EimIdentifierInfo structure indicates which identifier name has been provided. There is no guarantee that name will find a unique identifier. Therefore, using name can result in the return of multiple identifiers. The id values uniqueName, entryUUID and name can contain the wild card character, an asterisk (*).

lengthOfListData
(Input) The number of bytes the caller provides for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. The minimum size required is 20 bytes.

listData
(Output) A pointer to the EimList structure. The EimList structure contains information about the returned data. The data returned is a linked list of EimIdentifier structures. The firstEntry field in the EimList structure is used to get to the first EimIdentifier structure in the linked list. The number of completed EimIdentifier structures is returned in entriesReturned. The bytesReturned variable has the number of bytes the API used for the returned entries. If the number of entries returned is less than the number of entries available, the returned data contains as many complete EimIdentifier structures as will fit. It can also contain a partial EimIdentifier structure. The EimList structure follows:

typedef struct EimList
{  unsigned int bytesReturned;    /* Number of bytes actually returned by the API */
   unsigned int bytesAvailable;  /* Number of bytes of available data that could have been returned by the API */
   unsigned int entriesReturned; /* Number of entries actually returned by the API */
   unsigned int entriesAvailable; /* Number of entries available to be returned by the API */
   unsigned int firstEntry;      /* Displacement to the first linked list entry. This byte offset is relative to the start of the EimList structure. */
} EimList;

The EimIdentifier structure follows:

typedef struct EimIdentifier
{  unsigned int nextEntry;       /* Displacement to next entry. This byte offset is relative to the start of this structure */
   EimListData uniquename;       /* Unique name */
   EimListData description;      /* Description */
   EimListData entryUUID;        /* UUID */
   EimSubList names;             /* EimIdentifierName sublist */
   EimSubList additionalInfo;    /* EimAddlInfo sublist */
} EimIdentifier;

Identifiers might have defined several name attributes as well as several additional information attributes. In the EimIdentifier structure, the names EimSubList gives addressability to a linked list of EimIdentifierName structures. The EimIdentifierName follows:

typedef struct EimIdentifierName
{  unsigned int nextEntry;       /* Displacement to next entry. This byte offset is relative to the start of this structure */
   EimListData name;             /* Name */
} EimIdentifierName;
The additionalInfo EimSubList gives addressability to a linked list of EimAddlInfo structures. The EimAddlInfo structure follows:

```c
typedef struct EimAddlInfo {
    unsigned int nextEntry;         /* Displacement to next entry. This byte offset is relative to the start of this structure */
    EimListData addlInfo;           /* Additional info */
} EimAddlInfo;
```

The EimSubList structure follows:

```c
typedef struct EimSubList {
    unsigned int listNum;           /* Number of entries in the list */
    unsigned int disp;              /* Displacement to sublist. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimSubList;
```

The EimListData structure follows:

```c
typedef struct EimListData {
    unsigned int length;            /* Length of data */
    unsigned int disp;              /* Displacement to data. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimListData;
```

eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information
See the following:
• “eimAddIdentifier” on page 178
• “eimChangeIdentifier” on page 196
• “eimGetAssociatedIdentifiers” on page 243
• “eimRemoveIdentifier” on page 337

Authorization
EIM data
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:
• EIM administrator
• EIM registries administrator
• EIM identifiers administrator
• EIM registry X administrator
• EIM mapping lookup
The list returned contains only the information that the user has authority to access.

z/OS authorization
No special authorization is needed.
## Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>

        printf("%.%s\n",dataLength, data);
    else
        printf("Not found.\n");
eimListPolicyFilters

Purpose
Lists policy filters for the domain.

Format

```c
#include <eim.h>
int eimListPolicyFilters(EimHandle *eim,
                        enum EimPolicyFilterType *filterType,
                        char *registryName,
                        unsigned int lengthOfListData,
                        EimList *listData,
                        EimRC *eimrc)
```

Parameters

**eim**
(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

**filterType**
(Input) The type of policy filters to be listed. Valid values are:

- **EIM_ALL_FILTERS (0)** List all policy filters.
- **EIM_CERTIFICATE_FILTER (1)** List certificate policy filters.

**registryName**
(Input) The name of the X509 registry for which you want to list policy filters. If NULL is specified, then policy filters for the entire domain are listed.

**lengthOfListData**
(Input) The number of bytes provided by the caller for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. The minimum size is 20 bytes.

**listData**
(Output) A pointer to the EimList structure, which contains information about the returned data. The API returns as much data as space allows. The data returned is a linked list of EimPolicyFilter structures. The EimList structure follows:

```c
typedef struct EimList {
    unsigned int bytesReturned; /* Number of bytes actually returned by the API */
    unsigned int bytesAvailable; /* Number of bytes of available data that could have been returned by the API */
    unsigned int entriesReturned; /* Number of entries actually returned by the API */
    unsigned int entriesAvailable; /* Number of entries available to be returned by the API */
    unsigned int firstEntry; /* Displacement to the first linked list entry. This byte offset is relative to the start of the EimList structure. */
} EimList;
```
The EimPolicyFilter structure follows:

```c
typedef struct EimPolicyFilter
{
    unsigned int nextEntry;        /* Displacement to next entry. This byte offset is relative to the start of this structure */
    enum EimPolicyFilterType type; /* Type of policy filter. */
    EimListData sourceRegistry;    /* Source registry name this policy filter is defined for. */
    EimListData filterValue;       /* Policy filter value. */
} EimPolicyFilter;
```

The EimListData structure follows:

```c
typedef struct EimListData
{
    unsigned int length; /* Length of data */
    unsigned int disp;   /* Displacement to data. This byte offset is relative to the start of the parent structure; that is, the structure containing this structure. */
} EimListData;
```

eimrc

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information

See the following:

• “eimAddPolicyFilter” on page 185
• “eimRemovePolicyFilter” on page 343

Authorization

EIM data

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

• EIM administrator
• EIM registries administrator
• EIM identifiers administrator
• EIM Mapping Lookup
• EIM registry authority

The list returned (which can be empty) contains only the information that the user has authority to access.

z/OS authorization

No special authority is needed.

Example
The following example lists certificate policy filters for a registry.

```c
#include <eim.h>
#include <stddef.h>
#include <stdio.h>
#include <string.h>

void printListResults(EimList * list);
void printListData(char * fieldName, void * entry, int offset);

int main (int argc, char *argv[])
{
    int rc;
    char eimerr[200];
    EimRC * err;
    EimHandle handle;
    char listData[1000];
    EimList * list = (EimList *)listData;
    char * ldapHost = "ldap://localhost:389/ibm-eimDomainName=MyDomain,o=MyCompany,c=us";

    /* Set up error structure. */
    memset(eimerr,0x00,200);
    err = (EimRC *)eimerr;
    err->memoryProvidedByCaller = 200;

    con.type = EIM_SIMPLE;
    con.creds.simpleCreds.protect = EIM_PROTECT_NO;
    con.creds.simpleCreds.bindDn = "cn=administrator";
    con.creds.simpleCreds.bindPW = "secret";
    con.ssl = NULL;

    /* Create handle with specified LDAP URL */
    if (0 != (rc = eimCreateHandle(&handle, ldapHost, err)))
    {
        printf("Create handle error = %d\n", rc);
        return -1;
    }

    /* Connect with specified credentials */
    if (0 != (rc = eimConnect(&handle, con, err)))
    {
        printf("Connect error = %d\n", rc);
        eimDestroyHandle(&handle, err);
        return -1;
    }

    /* Get source registry policies */
    if (0 != (rc = eimListPolicyFilters(&handle,
                                        EIM_ALL_FILTERS,
                                        NULL,
                                        1000,
                                        list,
                                        err)))
    {
        printf("List EIM Policy Filters error = %d\n", rc);
        eimDestroyHandle(&handle, err);
        return -1;
    }

    /* Print the results */
    printListResults(list);

    /* Destroy the handle */
    rc = eimDestroyHandle(&handle, err);
    return 0;
}

void printListResults(EimList * list)
{
    int i;
    EimPolicyFilter * entry;

    printf("\n");
    printf("bytesReturned = %d\n", list->bytesReturned);
    printf("bytesAvailable = %d\n", list->bytesAvailable);
}
```
eimListRegistries

Purpose
Lists the user registries participating in the EIM domain. You can use the registryType, registryName and registryKind parameters to filter the results returned.

Format
#include <eim.h>

int eimListRegistries(EimHandle *eim, char *registryName, char *registryType, enum EimRegistryKind registryKind, unsigned int lengthOfListData, EimList *listData, EimRC *eimrc)
Parameters

**eim**
(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

**registryName**
(Input) The name of the EIM registry to list. The name can contain the wild card character, an asterisk (*). This is used as a filter to determine which registries to return. This parameter can be NULL; in this case, no filtering is done by name. Registry names are case-independent (meaning, not case-sensitive).

**registryType**
(Input) A string form of an OID that represents the registry type and a user name normalization method. The normalization method is necessary because some registries are case-independent and others are case-dependent. EIM uses this information to make sure the appropriate search occurs for registry user names.

The predefined registry types that EIM provides include the following:

- **EIM_REGTYPE_AIX**
- **EIM_REGTYPE_DOMINO_LONG**
- **EIM_REGTYPE_DOMINO_SHORT**
- **EIM_REGTYPE_KERBEROS_EX**
- **EIM_REGTYPE_KERBEROS_IG**
- **EIM_REGTYPE_LDAP**
- **EIM_REGTYPE_LINUX**
- **EIM_REGTYPE_NDS**
- **EIM_REGTYPE_OS400**
- **EIM_REGTYPE_POLICY_DIRECTOR**
- **EIM_REGTYPE_RACF**
- **EIM_REGTYPE_TIVOLI_ACCESS_MANAGER**
- **EIM_REGTYPE_WIN2K**
- **EIM_REGTYPE_WIN_DOMAIN_KERB_IG**
- **EIM_REGTYPE_WINDOWS_LOCAL_WS**
- **EIM_REGTYPE_X509**

You can also create your own registry type. This parameter can also be NULL; in this case, the API returns all registry types.

**registryKind**
(Input) The kind of registry to list. Valid values are:

- **EIM_ALL_REGISTRIES (0)**
  EIM returns both system and application registries.
- **EIM_SYSTEM_REGISTRY (1)**
  EIM returns only system registries.
- **EIM_APPLICATION_REGISTRY (2)**
  EIM returns only application registries.

**lengthOfListData**
(Input) The number of bytes the caller provides for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. The minimum size required is 20 bytes.
**listData**

(Output) A pointer to the data to return. The EimList structure contains information about the returned data. The data returned is a linked list of EimRegistry structures. The firstEntry field in the EimList structure is used to get to the first EimRegistry structure in the linked list. The number of completed EimRegistry structures is returned in entriesReturned. The bytesReturned variable has the number of bytes the API used for the returned entries. If the number of entries returned is less than the number of entries available, the returned data contains as many complete EimRegistry structures as will fit. It can also contain a partial EimRegistry structure. The EimList structure follows:

```c
typedef struct EimList {
    unsigned int bytesReturned;     /* Number of bytes actually returned by the API */
    unsigned int bytesAvailable;    /* Number of bytes of available data that could have been returned by the API */
    unsigned int entriesReturned;   /* Number of entries actually returned by the API */
    unsigned int entriesAvailable;  /* Number of entries available to be returned by the API */
    unsigned int firstEntry;        /* Displacement to the first linked list entry. This byte offset is relative to the start of the EimList structure. */
} EimList;
```

The EimRegistry structure follows:

```c
typedef struct EimRegistry {
    unsigned int nextEntry;         /* Displacement to next entry. This byte offset is relative to the start of this structure */
    enum EimRegistryKind kind;      /* Kind of registry */
    EimListData name;               /* Registry name */
    EimListData type;               /* Registry type */
    EimListData description;        /* Description */
    EimListData entryUUID;          /* Entry UUID */
    EimListData URI;                /* URI */
    EimListData systemRegistryName; /* System registry name */
    EimSubList registryAlias;       /* EimRegistryAlias sublist */
    enum EimStatus mappingLookup;   /* Mapping lookup attribute */
    enum EimStatus policyAssociations; /* Policy associations */
} EimRegistry;
```

Registries can have a number of defined aliases. In the EimRegistry structure, the registryAlias EimSubList gives addressability to the first EimRegistryAlias structure. The EimRegistryAlias structure follows:

```c
typedef struct EimRegistryAlias {
    unsigned int nextEntry;         /* Displacement to next entry. This byte offset is relative to the start of this structure */
    EimListData type;               /* Alias type */
    EimListData value;              /* Alias value */
} EimRegistryAlias;
```

The EimSubList structure follows:

```c
typedef struct EimSubList {
    unsigned int listNum;           /* Number of entries in the list */
    unsigned int disp;              /* Displacement to sublist. This byte offset is relative to the start of the parent structure i.e. the structure containing this structure */
} EimSubList;
```
The EimListData structure follows:

```c
typedef struct EimListData
{
  unsigned int length;            /* Length of data                 */
  unsigned int disp;              /* Displacement to data. This byte
                                  * offset is relative to the start of
                                  * the parent structure, i.e., the
                                  * structure containing this
                                  * structure.                     */
} EimListData;
```

**eimrc**

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

See the following:

- “eimAddApplicationRegistry” on page 170
- “eimAddSystemRegistry” on page 188
- “eimChangeRegistry” on page 200
- “eimRemoveRegistry” on page 346

**Authorization**

**EIM data**

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM registries administrator
- EIM identifiers administrator
- EIM registry X administrator
- EIM mapping lookup

The list returned (which can be empty) contains only the information that the user has authority to access.

**z/OS authorization**

No special authorization is needed.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>

            subentry = (EimRegistryAlias *)((char *)subentry +
                subentry->nextEntry);
        }
    }
}

**eimListRegistryAliases**

**Purpose**

Returns a list of all the aliases defined for a particular registry.

**Format**

```c
#include <eim.h>

int eimListRegistryAliases(EimHandle      *
eim,
    char *           registryName,
    unsigned int    lengthOfListData,
    EimList        * listData,
    EimRC          * eimrc)
```

**Parameters**

- **eim**
  - (Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.
registryName  
(Input) The name of the registry for which to list aliases. Registry names are case-independent (meaning, not case-sensitive).

The following special characters are not allowed in registry names:

, = + < > # ; \ *

lengthOfListData  
(Input) The number of bytes the caller provides for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. The minimum size required is 20 bytes.

listData  
(Output) A pointer to the data to return.

The EimList structure contains information about the returned data. The data returned is a linked list of EimRegistryAlias structures. The firstEntry field in the EimList structure is used to get to the first EimRegistryAlias structure in the linked list. The number of completed EimRegistryAlias structures is returned in entriesReturned. The bytesReturned variable has the number of bytes the API used for the returned entries. If the number of entries returned is less than the number of entries available, the returned data contains as many complete EimRegistryAlias structures as will fit. It can also contain a partial EimRegistryAlias structure. The EimList structure follows:

```c
typedef struct EimList
{
    unsigned int bytesReturned; /* Number of bytes actually returned by the API */
    unsigned int bytesAvailable; /* Number of bytes of available data that could have been returned by the API */
    unsigned int entriesReturned; /* Number of entries actually returned by the API */
    unsigned int entriesAvailable; /* Number of entries available to be returned by the API */
    unsigned int firstEntry; /* Displacement to the first linked list entry. This byte offset is relative to the start of the EimList structure. */
} EimList;
```

The EimRegistryAlias structure follows:

```c
typedef struct EimRegistryAlias
{
    unsigned int nextEntry; /* Displacement to next entry. This byte offset is relative to the start of this structure */
    EimListData type; /* Alias type */
    EimListData value; /* Alias value */
} EimRegistryAlias;
```

The EimListData follows:

```c
typedef struct EimListData
{
    unsigned int length; /* Length of data */
    unsigned int disp; /* Displacement to data. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimListData;
```

eimrc  
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.
Related Information

See the following:

- “eimChangeRegistryAlias” on page 203
- “eimGetRegistryNameFromAlias” on page 252

Authorization

EIM data

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM registries administrator
- EIM identifiers administrator
- EIM registry X administrator
- EIM mapping lookup

The returned list contains only the information that the user has authority to access, meaning it could be empty.

z/OS authorization

No special authorization is needed.

Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>

</table>
### Return Value | Meaning
---|---
EINVAL  | Input parameter was not valid.  
  - **EIMERR_EIMLIST_SIZE (16)**  
    Length of EimList is not valid. EimList must be at least 20 bytes in length.  
  - **EIMERR_HANDLE_INVAL (17)**  
    EimHandle is not valid.  
  - **EIMERR_PARM_REQ (34)**  
    Missing required parameter. Please check the API documentation.  
  - **EIMERR_PTR_INVAL (35)**  
    (z/OS does not return this value.) Pointer parameter is not valid.  
  - **EIMERR_SPACE (41)**  
    Unexpected error accessing parameter.  

ENOMEM  | Unable to allocate required space.  
  - **EIMERR_NOMEM (27)**  
    No memory available. Unable to allocate required space.  

ENOTCONN  | LDAP connection has not been made.  
  - **EIMERR_NOT_CONN (31)**  
    Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.  

EUNKNOWN  | Unexpected exception.  
  - **EIMERR_LDAP_ERR (23)**  
    Unexpected LDAP error.  
  - **EIMERR_UNKNOWN (44)**  
    Unknown error or unknown system state.

### Example
The following example lists all aliases for the specified registry:

```c
#include <eim.h>
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>

void printListResults(EimList * list);
void printListData(char * fieldName, void * entry, int offset);

int main(int argc, char *argv[])
{
    int            rc;
    char           eimerr[200];
    EimRC        * err;
    EimHandle      handle;
    EimConnectInfo con;
    char         * ldapHost = 
        "ldap://eimsystem:389/ibm-eimDomainName=myEimDomain,o=mycompany,c=us";
    char           listData[1000];
    EimList      * list = (EimList * ) listData;

    /* Set up error structure. */
    memset(eimerr,0x00,200);
    err = (EimRC *)eimerr;
    err->memoryProvidedByCaller = 200;

    con.type = EIM_SIMPLE;
    con.creds.simpleCreds.protect = EIM_PROTECT_NO;
    con.creds.simpleCreds.bindDn = "cn=administrator";
    con.creds.simpleCreds.bindPw = "secret";
    con.ssl = NULL;

doint main(int argc, char *argv[])
```
/* Create handle with specified LDAP URL */
if (0 != (rc = eimCreateHandle(&handle,
    ldapHost,
    err))) {
    printf("Create handle error = %d\n", rc);
    return -1;
}

/* Connect with specified credentials */
if (0 != (rc = eimConnect(&handle,
    con,
    err))) {
    printf("Connect error = %d\n", rc);
    eimDestroyHandle(&handle, err);
    return -1;
}

/* Get all aliases for the registry */
if (0 != (rc = eimListRegistryAliases(&handle,
    "MyRegistry",
    1000,
    list,
    err))) {
    printf("List registry aliases error = %d\n", rc);
    eimDestroyHandle(&handle, err);
    return -1;
}

/* Print the results */
printListResults(list);
rc = eimDestroyHandle(&handle, err);
return 0;

void printListResults(EimList * list)
{
    int i;
    EimRegistryAlias * entry;

    printf("___________\n");
    printf("   bytesReturned    = %d\n", list->bytesReturned);
    printf("   bytesAvailable   = %d\n", list->bytesAvailable);
    printf("   entriesReturned  = %d\n", list->entriesReturned);
    printf("   entriesAvailable = %d\n", list->entriesAvailable);
    printf("\n");

    entry = (EimRegistryAlias *)((char *)list + list->firstEntry);
    for (i = 0; i < list->entriesReturned; i++) {
        /* Print out results */
        printListData("Registry Alias Type",
            entry,
            offsetof(EimRegistryAlias, type));
        printListData("Registry Alias Value",
            entry,
            offsetof(EimRegistryAlias, value));

        /* advance to next entry */
        entry = (EimRegistryAlias *)((char *)entry + entry->nextEntry);
    }

    printf("\n");
}

void printListData(char * fieldName,
    void * entry,
    int offset)
{
    EimListData * listData;
    char * data;
    int dataLength;
eimListRegistryAssociations

Purpose
Lists association information for the registry or domain.

Format

```c
#include <eim.h>

int eimListRegistryAssociations(
    EimHandle               * eim,
    enum EimAssociationType associationType,
    char                     * registryName,
    char                     * registryUserName,
    unsigned int            lengthOfListData,
    EimList                 * listData,
    EimRC                   * eimrc)
```

Parameters

eim  
(Input) The EIM handle returned by a previous call to eimCreateHandle(). A valid connection is required for this function.

associationType  
(Input) The type of associations to be listed. Valid values are:

**EIM_ALL_ASSOC (0)**
List all associations.

**EIM_TARGET (1)**
List target associations. If this type is chosen, the following fields are returned:

- registryName
- registryUserName
- identifier
- targetMappingLookupStatus

Source associations found return the fields described under EIM_SOURCE and target associations found will return the fields listed under EIM_TARGET.

**EIM_SOURCE (2)**
List source associations. If this type is chosen, the following fields are returned:

- registryName
- registryUserName
- identifier
- sourceMappingLookupStatus
EIM_SOURCE_AND_TARGET (3)
List source and target associations. Source associations found will return the fields described under EIM_SOURCE, and target associations found will return the fields listed under EIM_TARGET.

EIM_ADMIN (4)
List administrative associations. If this type is chosen, the following fields are returned:
- registryName
- registryUserName
- identifier

EIM_ALL_POLICY_ASSOC (5)
List all policy associations. This returns all of the following policy associations: EIM_CERT_FILTER_POLICY, EIM_DEFAULT_REG_POLICY, EIM_DEFAULT_DOMAIN_POLICY, and EIM_DEFAULT_DOMAIN_POLICY.

EIM_CERT_FILTER_POLICY (6)
List certificate filter policy associations. If this type is chosen, the following fields are returned:
- registryName
- registryUserName
- sourceRegistry
- filterValue
- domainPolicyAssocStatus
- sourceMappingLookupStatus
- targetMappingLookupStatus
- targetPolicyAssocStatus

EIM_DEFAULT_REG_POLICY (7)
List default registry policy associations. If this type is chosen, the following fields are returned:
- registryName
- registryUserName
- sourceRegistry
- domainPolicyAssocStatus
- sourceMappingLookupStatus
- targetMappingLookupStatus
- targetPolicyAssocStatus

EIM_DEFAULT_DOMAIN_POLICY (8)
List default domain policy associations. If this type is chosen, the following fields are returned:
- registryName
- registryUserName
- domainPolicyAssocStatus
- targetMappingLookupStatus
- targetPolicyAssocStatus

registryName
(Input) The name of the registry for which to list association information.

registryUserName
(Input) The name of the registry user name for which to list association information.

lengthOfListData
(Input) The number of bytes provided by the caller for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number.
as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the
data. The minimum size is 20 bytes.

**listData**

(Output) A pointer to the EimList structure, which contains information about the returned data. The
API will return as much data as space has allowed. The data returned is a linked list of
EimRegistryAssociation structures. The EimList structure follows:

```c
typedef struct EimList
{
    unsigned int bytesReturned;     /* Number of bytes actually returned
        by the API                      */
    unsigned int bytesAvailable;    /* Number of bytes of available data
        that could have been returned by
        the API                           */
    unsigned int entriesReturned;   /* Number of entries actually
        returned by the API              */
    unsigned int entriesAvailable;  /* Number of entries available to be
        returned by the API              */
    unsigned int firstEntry;        /* Displacement to the first linked
        list entry. This byte offset is
        relative to the start of the
        EimList structure.               */
} EimList;
```

The EimRegistryAssociation structure follows:

```c
typedef struct EimRegistryAssociation
{
    unsigned int nextEntry;         /* Displacement to next entry.  This
        byte offset is relative to the
        start of this structure          */
    enum EimAssociationType type;   /* Type of association.           */
    EimListData registryName;       /* Registry name the association
        is defined to.                   */
    EimListData registryUserName;   /* Registry user name the
        association is defined to.       */
    EimListData identifier;         /* Unique name for eim identifier.*/
    EimListData sourceRegistry;     /* Source registry name the
        association is defined for.      */
    EimListData filterValue;        /* Filter value.                */
    enum EimPolicyStatus domainPolicyAssocStatus;
        /* Policy association status for the domain:
        0 = not enabled
        1 = enabled                     */
    enum EimPolicyStatus sourceMappingLookupStatus;
        /* Mapping lookup status for the
        source registry:
        0 = not enabled
        1 = enabled                     */
    enum EimPolicyStatus targetMappingLookupStatus;
        /* Mapping lookup status for the
        target registry:
        0 = not enabled
        1 = enabled                     */
    enum EimPolicyStatus targetPolicyAssocStatus;
        /* Policy association status for
        the target registry:
        0 = not enabled
        1 = enabled                     */
} EimRegistryAssociation;
```

The EimListData structure follows:

```c
typedef struct EimListData
{
    unsigned int length;            /* Length of data                 */
    unsigned int disp;              /* Displacement to data.  This byte
        offset is relative to the start of
        the parent structure; that is, the
        structure containing this
        structure.                      */
} EimListData;
```
eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information
See the following:
• “eimAddPolicyAssociation” on page 181
• “eimAddAssociation” on page 174
• “eimGetAssociatedIdentifiers” on page 243

Authorization
EIM data
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:
• EIM administrator
• EIM registries administrator
• EIM identifiers administrator
• EIM mapping lookup
• EIM authority to an individual registry
The returned list contains only the information that the user has authority to access, meaning it could be empty.

z/OS authorization
No special authorization is needed.

eimListRegistryUsers

Purpose

Lists the users in a particular registry that have target associations defined.

Format

```
#include <eim.h>

int eimListRegistryUsers(EimHandle *eim, char *registryName, char *registryUserName, unsigned int lengthOfListData, EimList *listData, EimRC *eimrc)
```

Parameters

- **eim**
  (Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

- **registryName**
  (Input) The name of the registry that contains this user. Registry names are case-independent (meaning, not case-sensitive).
  
  The following special characters are not allowed in registry names:
  
  `, = + < > # ; \ *`

- **registryUserName**
  (Input) The name of the user to list in this registry. NULL indicates listing all users. The registry user name should begin with a non-blank character.

- **lengthOfListData**
  (Input) The number of bytes the caller provides for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. The minimum size required is 20 bytes.

- **listData**
  (Output) A pointer to the EimList structure. The EimList structure contains information about the returned data. The data returned is a linked list of EimRegistryUser structures. The firstEntry field in the EimList structure is used to get to the first EimRegistryUser structure in the linked list. The number of completed EimRegistryUser structures is returned in entriesReturned. The bytesReturned variable has the number of bytes the API used for the returned entries. If the number of entries returned is less than the number of entries available, the returned data contains as many complete EimRegistryUser structures as will fit. It can also contain a partial EimRegistryUser structure. The EimList structure follows:

```c
typedef struct EimList {
    unsigned int bytesReturned; /* Number of bytes actually returned by the API */
} EimList;
```
unsigned int bytesAvailable; /* Number of bytes of available data that could have been returned by the API */
unsigned int entriesReturned; /* Number of entries actually returned by the API */
unsigned int entriesAvailable; /* Number of entries available to be returned by the API */
unsigned int firstEntry; /* Displacement to the first linked list entry. This byte offset is relative to the start of the EimList structure. */
}
} EimList;

The EimRegistryUser structure follows:

typedef struct EimRegistryUser
{
    unsigned int nextEntry; /* Displacement to next entry. This byte offset is relative to the start of this structure. */
    EimListData registryUserName; /* Name */
    EimListData description; /* Description */
    EimSubList additionalInfo; /* EimAddlInfo sublist */
} EimRegistryUser;

Registry users might have defined several additional attributes. In the EimRegistryUser structure, additionalInfo gives addressability to the first EimAddlInfo structure that contains a linked list of attributes. The EimAddlInfo structure follows:

typedef struct EimAddlInfo
{
    unsigned int nextEntry; /* Displacement to next entry. This byte offset is relative to the start of this structure. */
    EimListData addlInfo; /* Additional info */
} EimAddlInfo;

The EimSubList structure follows:

typedef struct EimSubList
{
    unsigned int listNum; /* Number of entries in the list */
    unsigned int disp; /* Displacement to sublist. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimSubList;

The EimListData structure follows:

typedef struct EimListData
{
    unsigned int length; /* Length of data */
    unsigned int disp; /* Displacement to data. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimListData;

eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information

See the following:

• “eimChangeRegistryUser” on page 207
Authorization

**EIM data**

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM registries administrator
- EIM identifiers administrator
- EIM registry X administrator
- EIM mapping lookup

The list returned contains only the information that the user has authority to access.

**z/OS authorization**

No special authorization is needed.

Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful. Check the entriesReturned member of the listData to determine if any entries were returned.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>
</tr>
<tr>
<td>EBADDATA</td>
<td>eimrc is not valid.</td>
</tr>
<tr>
<td>EBADNAME</td>
<td>Registry not found or insufficient access to EIM data.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>Unable to allocate internal system object.</td>
</tr>
<tr>
<td>ECONVERT</td>
<td>Data conversion error.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Input parameter was not valid.</td>
</tr>
<tr>
<td>EIMERR_EIMLIST_SIZE</td>
<td>Length of EimList is not valid. EimList must be at least 20 bytes in length.</td>
</tr>
<tr>
<td>EIMERR_HANDLEINVAL</td>
<td>EimHandle is not valid.</td>
</tr>
<tr>
<td>EIMERR_PARM_REQ</td>
<td>Missing required parameter. Please check the API documentation.</td>
</tr>
<tr>
<td>EIMERR_PTRINVAL</td>
<td>(z/OS does not return this value.) Pointer parameter is not valid.</td>
</tr>
<tr>
<td>EIMERR_SPACE</td>
<td>Unexpected error accessing parameter.</td>
</tr>
</tbody>
</table>
### Return Value | Meaning
--- | ---
ENOMEM | Unable to allocate required space.  
**EIMERR_NOMEM (27)**  
No memory available. Unable to allocate required space.

ENOTCONN | LDAP connection has not been made.  
**EIMERR_NOT_CONN (31)**  
Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.

EUNKNOWN | Unexpected exception.  
**EIMERR_LDAP_ERR (23)**  
Unexpected LDAP error.  
**EIMERR_UNEXP_OBJ_VIOLATION (56)**  
Unexpected object violation.  
**EIMERR_UNKNOWN (44)**  
Unknown error or unknown system state.

### Example

The following example lists all users in the specified registry:

```c
#include <eim.h>
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>

void printListResults(EimList * list);
void printSubListData(char * fieldName, void * entry, int offset);
void printListData(char * fieldName, void * entry, int offset);

int main(int argc, char * argv[])
{
    int            rc;
    char           eimerr[200];
    EimRC        * err;
    EimHandle      handle;
    EimConnectInfo con;
    char         * ldapHost =
        "ldap://eimsystem:389/ibm-eimDomainName=myEimDomain,o=mycompany,c=us";
    char          listData[1000];
    EimList     * list = (EimList * ) listData;

    /* Set up error structure.                  */
    memset(eimerr,0x00,200);
    err = (EimRC *)eimerr;
    err->memoryProvidedByCaller = 200;
    con.type = EIM_SIMPLE;
    con.creds.simpleCreds.protect = EIM_PROTECT_NO;
    con.creds.simpleCreds.bindDn = "cn=admin";
    con.creds.simpleCreds.bindPw = "secret";
    con.ssl = NULL;

    /* Create handle with specified LDAP URL    */
    if (0 != (rc = eimCreateHandle(&handle,  
        ldapHost,   
        err))) {
        printf("Create handle error = \%d\n", rc);
        return -1;
    }

    EimListData * listData;
    char * data;
    int dataLength;
    printf("%s = ",fieldName);
    /* Address the EimListData object */
    listData = (EimListData *)((char *)entry + offset);
    /* Print out results */
    data = (char *)entry + listData->disp;
    dataLength = listData->length;
    if (dataLength > 0)
        printf("%.*s\n",dataLength, data);
    else
        printf("Not found.\n");
}

---

eimListUserAccess

**Purpose**

Lists the access groups of which the given user is a member.

**Format**

```
#include <eim.h>

int eimListUserAccess(EimHandle      * eim,
                       EimAccessUser  * accessUser,
                       unsigned int lengthOfListData,
                       EimList        * listData,
                       EimRC          * eimrc)
```

**Parameters**

**eim**

(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

**accessUser**

(Input) A structure that contains the user information for which to retrieve access.

**EIM_ACCESS_DN**

Indicates a distinguished name defined in an LDAP directory that can be used to bind to the EIM domain.

**EIM_ACCESS_LOCAL_USER**

(z/OS does not support this; for RACF user IDs, use EIM_ACCESS_DN instead.)
EIM_ACCESS_LOCAL_USER indicates a local user name on the system where the API runs. EIM converts the local user name to the appropriate access ID for this system.

**EIM_ACCESS_KERBEROS**

Indicates a Kerberos principal. EIM converts the Kerberos principal to the appropriate access ID, for example, converting petejones@therealm to ibm-kn=petejones@threalm.
The EimAccessUser structure layout follows:

```c
enum EimAccessUserType {
    EIM_ACCESS_DN,
    EIM_ACCESS_KERBEROS,
    EIM_ACCESS_LOCAL_USER
};

typedef struct EimAccessUser {
    union {
        char * dn;
        char * kerberosPrincipal;
        char * localUser;
    } user;
    enum EimAccessUserType userType;
} EimAccessUser;
```

**lengthOfListData**

(Input) The number of bytes the caller provides for the listData parameter. If the value of bytesReturned is less than bytesAvailable in the returned listData structure, you can use this number as the bytesAvailable size, update the lengthOfListData parameter, and reissue the API to retrieve the data. The minimum size required is 20 bytes.

**listData**

(Output) A pointer to the EimList structure. The EimList structure contains information about the returned data. The data returned is a linked list of EimUserAccess structures. The firstEntry field in the EimList structure is used to get to the first EimUserAccess structure in the linked list. The number of completed EimUserAccess structures is returned in entriesReturned. The bytesReturned variable has the number of bytes the API used for the returned entries. If the number of entries returned is less than the number of entries available, the returned data contains as many complete EimUserAccess structures as will fit. It can also contain a partial EimUserAccess structure, but not a partial entry. The EimList structure follows:

```c
typedef struct EimList {
    unsigned int bytesReturned;     /* Number of bytes actually returned
                                    by the API.                      */
    unsigned int bytesAvailable;    /* Number of bytes of available data
                                    that could have been returned by
                                    the API.                         */
    unsigned int entriesReturned;   /* Number of entries actually
                                    returned by the API.             */
    unsigned int entriesAvailable;  /* Number of entries available to be
                                    returned by the API.             */
    unsigned int firstEntry;        /* Displacement to the first linked
                                    list entry. This byte offset is
                                    relative to the start of the
                                    EimList structure.               */
} EimList;
```

The EimUserAccess structure follows:

```c
typedef struct EimUserAccess {
    unsigned int nextEntry;         /* Displacement to next entry.  This
                                    byte offset is relative to the
                                    start of this structure.         */
    enum EimAccessIndicator eimAdmin;
    enum EimAccessIndicator eimRegAdmin;
    enum EimAccessIndicator eimIdenAdmin;
    enum EimAccessIndicator eimMappingLookup;
    EimSubList registries;          /* EimRegistryName sublist        */
} EimUserAccess;
```

The registries EimSubList gives addressability to a linked list of EimRegistryName structures. The EimRegistryName structure follows:

```c
typedef struct EimRegistryName {
    unsigned int nextEntry;         /* Displacement to next entry.  This
                                    byte offset is relative to the
                                    start of this structure.         */
} EimRegistryName;
```
The EimSubList structure follows:

```c
typedef struct EimSubList {
    unsigned int listNum;           /* Number of entries in the list */
    unsigned int disp;              /* Displacement to sublist. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimSubList;
```

The EimListData structure follows:

```c
typedef struct EimListData {
    unsigned int length;            /* Length of data */
    unsigned int disp;              /* Displacement to data. This byte offset is relative to the start of the parent structure, i.e. the structure containing this structure. */
} EimListData;
```

**eimrc**

(Input) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

See the following:

- “eimAddAccess” on page 167
- “eimListAccess” on page 271
- “eimRemoveAccess” on page 330
- “eimQueryAccess” on page 326

**Authorization**

**EIM data**

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator

  The list returned contains only the information that the user has authority to access.

**z/OS authorization**

No special authorization is needed.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>

<td>Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.</td>
</tr>
<tr>
<td>EUNKNOWN</td>
<td>Unexpected exception.</td>
</tr>
<tr>
<td><strong>EIMERR_LDAP_ERR (23)</strong></td>
<td>Unexpected LDAP error.</td>
</tr>
<tr>
<td><strong>EIMERR_UNKNOWN (44)</strong></td>
<td>Unknown error or unknown system state.</td>
</tr>
</tbody>
</table>

**Example**

The following example will list the access for the user with distinguished name "cn=pete,o=ibm,c=us".

```c
#include <eim.h>
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>
void printListResults(EimList * list);
void printSubListData(char * fieldName, void * entry, int offset);
void printListData(char * fieldName, void * entry, int offset);
int main(int argc, char *argv[])
{
    int rc;
    char eimerr[200];
    EimRC * err;
    // Example code here...
}
```
EimHandle handle;
EimAccessUser user;
EimConnectInfo con;
char listData[1000];
EimList *list = (EimList *)listData;
char *ldapHost =
"ldap://eimsystem:389/ibm-eimDomainName=myEimDomain,o=mycompany,c=us";

/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;
con.type = EIM_SIMPLE;
con.creds.simpleCreds.protect = EIM_PROTECT_NO;
con.creds.simpleCreds.bindDn = "cn=admin";
con.creds.simpleCreds.bindPwd = "secret";
con.ssl = NULL;

/* Create handle with specified LDAP URL */
if (0 != (rc = eimCreateHandle(&handle, ldapHost, err))) {
    printf("Create handle error = %d\n", rc);
    return -1;
}

/* Connect with specified credentials */
if (0 != (rc = eimConnect(&handle, con, err))) {
    printf("Connect error = %d\n", rc);
    eimDestroyHandle(&handle, err);
    return -1;
}

/* Set up access user information */
user.userType = EIM_ACCESS_DN;
user.user.dn = "cn=pete,o=ibm,c=us";

/* Get user accesses */
if (0 != (rc = eimListUserAccess(&handle, &user, 1000, list, err))) {
    printf("List user access error = %d\n", rc);
    eimDestroyHandle(&handle, err);
    return -1;
}

/* Print the results */
printListResults(list);

/* Destroy the handle */
rc = eimDestroyHandle(&handle, err);
return 0;
}

void printListResults(EimList *list) {
    int i;
    EimUserAccess *entry;
    EimListData *listData;
    EimRegistryName *registry;
    printf("\n");
    printf("  bytesReturned = %ld\n", list->bytesReturned);
    printf("  bytesAvailable = %ld\n", list->bytesAvailable);
    printf("  entriesReturned = %ld\n", list->entriesReturned);
    printf("  entriesAvailable = %ld\n", list->entriesAvailable);
    printf("\n");
    if (list->entriesReturned > 1)
        printf("Unexpected number of entries returned.\n");
    entry = (EimUserAccess *)(char *)list + list->firstEntry;
    if (EIM_ACCESS_YES == entry->eimAdmin)
        printf(" EIM Admin.\n");
    if (EIM_ACCESS_YES == entry->eimRegAdmin)
# eimQueryAccess

## Purpose

Queries to check if the user has the specified access.

## Format

```c
#include <eim.h>

int eimQueryAccess(EimHandle *eim, EimAccessUser *accessUser, enum EimAccessType accessType, char *registryName);
```
Parameters

eim
(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

accessUser
(Input) A structure that contains the user information for which to query access.

**EIM_ACCESS_DN**
Indicates a distinguished name defined in an LDAP directory that you can use to bind to the EIM domain.

**EIM_ACCESS_LOCAL_USER**
(z/OS does not support this. Use EIM_ACCESS_DN instead.) It indicates a local user name on the system where the API runs. The local user name is converted to the appropriate access ID for this system.

**EIM_ACCESS_KERBEROS**
Indicates a Kerberos identity. The Kerberos identity is converted to the appropriate access ID. For example, EIM converts petejones@therealm to ibm-kn=petejones@threalm.

The EimAccessUser structure layout follows:

```c
enum EimAccessUserType {
    EIM_ACCESS_DN,
    EIM_ACCESS_KERBEROS,
    EIM_ACCESS_LOCAL_USER
};

typedef struct EimAccessUser {
    union {
        char * DN;
        char * kerberosPrincipal;
        char * localUser;
    } user;
    enum EimAccessUserType userType;
} EimAccessUser;
```

accessType
(Input) The type of access to check. Valid values are:

**EIM_ACCESS_ADMIN (0)**
Administrative authority to the entire EIM domain.

**EIM_ACCESS_REG_ADMIN (1)**
Administrative authority to all registries in the EIM domain.

**EIM_ACCESS_REGISTRY (2)**
Administrative authority to the registry specified in the registryName parameter.

**EIM_ACCESS_IDENTIFIER_ADMIN (3)**
Administrative authority to all of the identifiers in the EIM domain.

**EIM_ACCESS_MAPPING_LOOKUP (4)**
Authority to perform mapping lookup operations.

registryName
(Input) The name of the EIM registry for which to check the access. Registry names are case-independent (not case-sensitive). This parameter is used only if accessType is EIM_ACCESS_REGISTRY. If accessType is anything other than EIM_ACCESS_REGISTRY, this parameter must be NULL.

The following special characters are not allowed in registry names:

, = + < > # ; \ *

**accessIndicator**  
(Output) Indicates whether access is found.

**EIM_ACCESS_NO (0)**  
Access not found.

**EIM_ACCESS_YES (1)**  
Access found.

**eimrc**  
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

See the following:

- “eimAddAccess” on page 167
- “eimListAccess” on page 271
- “eimListUserAccess” on page 321
- “eimRemoveAccess” on page 330

**Authorization**

**EIM data**

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator

**z/OS authorization**

No special authorization is needed.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>
</tr>
<tr>
<td>EBADDATA</td>
<td>eimrc is not valid.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>Unable to allocate internal system object.</td>
</tr>
</tbody>
</table>

**EIMERR_NOLOCK (26)**

(z/OS does not return this value.) Unable to allocate internal system object.

<table>
<thead>
<tr>
<th>ECONVERT</th>
<th>Data conversion error.</th>
</tr>
</thead>
</table>

**EIMERR_DATA_CONVERSION (13)**

(z/OS does not return this value.) Error occurred when converting data between code pages.
<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Input parameter was not valid.</td>
</tr>
<tr>
<td>EIMERR_ACCESS_TYPE_INVAL (2)</td>
<td>Access type is not valid.</td>
</tr>
<tr>
<td>EIMERR_ACCESS_USERTYPE_INVAL (3)</td>
<td>Access user type is not valid.</td>
</tr>
<tr>
<td>EIMERR_HANDLE_INVAL (17)</td>
<td>EimHandle is not valid.</td>
</tr>
<tr>
<td>EIMERR_PARM_REQ (34)</td>
<td>Missing required parameter. Please check the API documentation.</td>
</tr>
<tr>
<td>EIMERR_PTR_INVAL (35)</td>
<td>(z/OS does not return this value.) Pointer parameter is not valid.</td>
</tr>
<tr>
<td>EIMERR_REG_MUST_BE_NULL (55)</td>
<td>Registry name must be NULL when access type is not EIM_ACCESS_REGISTRY.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Unable to allocate required space.</td>
</tr>
<tr>
<td>EIMERR_NOMEM (27)</td>
<td>No memory available. Unable to allocate required space.</td>
</tr>
<tr>
<td>ENOTCONN</td>
<td>LDAP connection has not been made.</td>
</tr>
<tr>
<td>EIMERR_NOT_CONN (31)</td>
<td>Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.</td>
</tr>
<tr>
<td>EUNKNOWN</td>
<td>Unexpected exception.</td>
</tr>
<tr>
<td>EIMERR_LDAP_ERR (23)</td>
<td>Unexpected LDAP error.</td>
</tr>
<tr>
<td>EIMERR_UNKNOWN (44)</td>
<td>Unknown error or unknown system state.</td>
</tr>
</tbody>
</table>

**Example**

The following illustrates a query to see if the distinguished name "cn=pete,o=ibm,c=us" is a member of the "EIM Administrator" access group.

```c
#include <eim.h>

int           rc;
char          eimerr[200];
EimRC       * err;
EimHandle     handle;
EimAccessUser user;
unsigned int indicator;

/* Set up error structure.                  */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Set up access user info                  */
user.userType = EIM_ACCESS_DN;
user.user.DN="cn=pete,o=ibm,c=us";

/* Query access for this user.              */
```
eimRemoveAccess

Purpose

Removes the user from an EIM access group.

Format

```
#include <eim.h>

int eimRemoveAccess(EimHandle *eim, EimAccessUser *accessUser, enum EimAccessType accessType, char *registryName, EimRC *eimrc);
```

Parameters

- **eim**
  (Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

- **accessUser**
  (Input) A structure that contains the user information from which to remove access.

  **EIM_ACCESS_DN**
  Indicates a distinguished name defined in an LDAP directory that you can use to bind to the EIM domain.

  **EIM_ACCESS_LOCAL_USER**
  (z/OS does not support this. Use EIM_ACCESS_DN instead.) It indicates a local user name on the system where the API runs. The local user name is converted to the appropriate access ID for this system.

  **EIM_ACCESS_KERBEROS**
  Indicates a Kerberos identity. The Kerberos identity is converted to the appropriate access ID. For example, EIM converts petejones@therealm to ibm-kn=petejones@therealm.

The EimAccessUser structure layout follows:

```c
enum EimAccessType {
  EIM_ACCESS_DN, EIM_ACCESS_KERBEROS, EIM_ACCESS_LOCAL_USER
};

typedef struct EimAccessUser {
  union {
    char * DN;
    char * kerberosPrincipal;
    char * localUser;
  } user;
  enum EimAccessType userType;
} EimAccessUser;
```
**accessType**

(Input) The type of access to remove. Valid values are:

- **EIM_ACCESS_ADMIN (0)**
  Administrative authority to the entire EIM domain.

- **EIM_ACCESS_REG_ADMIN (1)**
  Administrative authority to all registries in the EIM domain.

- **EIM_ACCESS_REGISTRY (2)**
  Administrative authority to the registry specified in the registryName parameter.

- **EIM_ACCESS_IDENTIFIER_ADMIN (3)**
  Administrative authority to all of the identifiers in the EIM domain.

- **EIM_ACCESS_MAPPING_LOOKUP (4)**
  Authority to perform mapping lookup operations.

**registryName**

(Input) The name of the registry from which to remove access. Registry names are case-independent (meaning, not case-sensitive). This parameter is used only if accessType is EIM_ACCESS_REGISTRY. If accessType is anything other than EIM_ACCESS_REGISTRY, this parameter must be NULL.

The following special characters are not allowed in registry names:

```
, = + < > # ; \ *
```

**eimrc**

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

See the following:

- “eimAddAccess” on page 167
- “eimListAccess” on page 271
- “eimListUserAccess” on page 321
- “eimQueryAccess” on page 326

**Authorization**

**EIM data**

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator

**z/OS authorization**

No special authorization is needed.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>

<td>Unknown error or unknown system state.</td>
</tr>
</tbody>
</table>

**Example**

The following illustrates removing the distinguished name(DN) of a user from the EIM Administor access group:

```c
#include <eim.h>
```
int           rc;
char          eimerr[200];
EimRC       * err;
EimHandle     handle;
EimAccessUser user;

/* Set up error structure.                  */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Set user information                     */
user.userType = EIM_ACCESS_DN;
user.user.DN="cn=pete,o=ibm,c=us";

/* Remove access for this user.             */
rc = eimRemoveAccess(&handle,
                        &user,
                        EIM_ACCESS_ADMIN,
                        NULL,
                        err);

---

**eimRemoveAssociation**

**Purpose**

Removes an association for a user in a specified user registry with an EIM identifier.

**Format**

```c
#include <eim.h>

int eimRemoveAssociation(EimHandle               * eim,
                           enum EimAssociationType associationType,
                           EimIdentifierInfo       * idName,
                           char                    * registryName,
                           char                    * registryUserName,
                           EimRC                   * eimrc)
```

**Parameters**

- **eim**
  - (Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

- **associationType**
  - (Input) The type of association to remove. Valid values are:
    - **EIM_ALL_ASSOC (0)**
      - Remove all associations.
    - **EIM_TARGET (1)**
      - Remove a target association.
    - **EIM_SOURCE (2)**
      - Remove a source association.
    - **EIM_SOURCE_AND_TARGET (3)**
      - Remove both a source association and a target association.
EIM_ADMIN (4)
Remove an administrative association.

idName
(Input) A structure that contains the identifier name from which to remove this association. The layout of the EimIdentifierInfo structure follows:

```c
enum EimIdType {
    EIM_UNIQUE_NAME,
    EIM_ENTRY_UUID,
    EIM_NAME
};

typedef struct EimIdentifierInfo {
    union {
        char       * uniqueName;
        char       * entryUUID;
        char       * name;
    } id;
    enum EimIdType        idtype;
} EimIdentifierInfo;
```

idtype
The idtype in the EimIdentifierInfo structure indicates which identifier name has been provided. EIM_UNIQUE_NAME finds at most one matching identifier. EIM_NAME results in an error if your EIM domain has more than one identifier containing the same name.

registryName
(Input) The registry name. Registry names are case-independent (meaning, not case-sensitive).
The following special characters are not allowed in registry names:

```
, = + < > # ; \ *
```

registryUserName
(Input) The registry user name. This can be normalized according to the normalization method for defined registry. The registry user name should begin with a non-blank character.

eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information
See the following:

- “eimAddAssociation” on page 174
- “eimGetAssociatedIdentifiers” on page 243
- “eimListAssociations” on page 275

Authorization

EIM data
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The authority that the access group has to the EIM data depends on the type of association being removed.

For administrative and source associations, the access groups whose members have authority to the EIM data for this API follow:

- EIM Administrator
- EIM identifiers administrator
For target associations, the access groups whose members have authority to the EIM data for this API follow:

- EIM Administrator
- EIM registries administrator
- EIM registry \(X\) administrator

**z/OS authorization**

No special authorization is needed.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the `messageCatalogMessageID` field in the `eimrc` parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>
</tr>
</tbody>
</table>
|              | **EIMERR_ACCESS (1)**  
|              |    Insufficient access to EIM data. |
| EBADDATA     | `eimrc` is not valid. |
| EBADNAME     | Registry or identifier name is not valid or insufficient access to EIM data. |
|              | **EIMERR_IDNAME_AMBIGUOUS (20)**  
|              |    More than one EIM identifier was found that matches the requested identifier name. |
|              | **EIMERR_NOIDENTIFIER (25)**  
|              |    EIM identifier not found or insufficient access to EIM data. |
|              | **EIMERR_NOREG (28)**  
|              |    EIM registry not found or insufficient access to EIM data. |
| EBUSY        | Unable to allocate internal system object. |
|              | **EIMERR_NOLOCK (26)**  
|              |    (z/OS does not return this value.) Unable to allocate internal system object. |
| ECONVERT     | Data conversion error. |
|              | **EIMERR_DATA_CONVERSION (13)**  
|              |    (z/OS does not return this value.) Error occurred when converting data between code pages. |
| EINVAL       | Input parameter was not valid. |
|              | **EIMERR_ASSOC_TYPE_INVAL (4)**  
|              |    Association type is not valid. |
|              | **EIMERR_HANDLE_INVAL (17)**  
|              |    EimHandle is not valid. |
|              | **EIMERR_IDNAME_TYPE_INVAL (52)**  
|              |    The EimIdType value is not valid. |
|              | **EIMERR_PARM_REQ (34)**  
|              |    Missing required parameter. Please check the API documentation. |
|              | **EIMERR_PTR_INVAL (35)**  
|              |    (z/OS does not return this value.) Pointer parameter is not valid. |
### Return Value | Meaning
---|---
EMVSERR | An MVS environment or internal error has occurred.

- **EIMERR_ZOS_DATA_CONVERSION (6011)**
  Error occurred when converting data between code pages.

ENOMEM | Unable to allocate required space.

- **EIMERR_NOMEM (27)**
  No memory available. Unable to allocate required space.

ENOTCONN | LDAP connection has not been made.

- **EIMERR_NOT_CONN (31)**
  Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.

EROMFS | LDAP connection is for read-only. Need to connect to master.

- **EIMERR_READ_ONLY (36)**
  This LDAP connection has "read-only" access. A connection to the master LDAP server with read/write is required to complete the operation. Use the eimConnectToMaster API to get a write connection.

EUNKNOWN | Unexpected exception.

- **EIMERR_LDAP_ERR (23)**
  Unexpected LDAP error.

- **EIMERR_UNEXP_OBJ_VIOLATION (56)**
  Unexpected object violation.

- **EIMERR_UNKNOWN (44)**
  Unknown error or unknown system state.

### Example
The following illustrates removing an administrative, source, and target association for a specified identifier:

```c
#include <eim.h>
#include <stdio.h>

int               rc;
char              eimerr[200];
EimRC           * err;
EimHandle         handle;
EimIdentifierInfo x;

/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Set up identifier information. */
x.idtype = EIM_UNIQUE_NAME;
x.id.uniqueName = "mjones";

/* Remove an Admin association */
rc = eimRemoveAssociation(&handle,
EIM_ADMIN,
&x,
"MyRegistry",
"maryjones",
err);
```
eimRemoveIdentifier

Purpose

Removes an EIM identifier and all of its associated mappings from the EIM domain.

Format

```c
#include <eim.h>

int eimRemoveIdentifier(EimHandle *eim,
                           EimIdentifierInfo *idName,
                           EimRC *eimrc)
```

Parameters

**eim**

(Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

**idName**

(Input) A structure that contains the name for this identifier. EIM_NAME returns either one matching identifier or an error if your EIM domain has more than one identifier with the same non-unique name. The layout of the EimIdentifierInfo structure follows:

```c
enum EimIdType {
    EIM_UNIQUE_NAME,
    EIM_ENTRY_UUID,
    EIM_NAME
};

typedef struct EimIdentifierInfo {
    union {
        char   * uniqueName;
        char   * entryUUID;
        char   * name;
    } id;
    enum EimIdType        idtype;
} EimIdentifierInfo;
```
idtype
The idtype in the EimIdentifierInfo structure indicates which identifier name has been provided.
EIM_UNIQUE_NAME finds at most one matching identifier. EIM_NAME results in an error if your
EIM domain has more than one identifier containing the same name.

eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM
sets eimrc with additional information. This parameter can be NULL. For the format of the structure,
see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information
See the following:
• “eimAddIdentifier” on page 178
• “eimChangeIdentifier” on page 196
• “eimGetAssociatedIdentifiers” on page 243
• “eimListIdentifiers” on page 287

Authorization
EIM data
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The
access groups whose members have authority to the EIM data for this API follow:
• EIM administrator

z/OS authorization
No special authorization is needed.

Return Values
The following table lists the return values from the API. Following each return value is the list of possible
values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>

</tr>
</tbody>
</table>

**Example**

The following example illustrates removing an EIM identifier:

```c
#include <eim.h>

int rc;  char eimerr[200];  EimRC * err;  EimHandle handle;  EimIdentifierInfo idInfo;

/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;
```
/* Set identifier information. */
idInfo.idtype = EIM_UNIQUE_NAME;
idInfo.id.uniqueName = "Mary Smith";

/* Remove this identifier. */
rc = eimRemoveIdentifier(&handle, &idInfo, err);

---

**eimRemovePolicyAssociation**

**Purpose**

Removes the specified policy association from the domain.

**Format**

```c
#include <eim.h>
int eimRemovePolicyAssociation(EimHandle eim, EimPolicyAssociationInfo policyAssoc, EimRC eimrc)
```

**Parameters**

*eim*

(Input) The EIM handle returned by a previous call to eimCreateHandle. A valid connection is required for this function.

*policyAssoc*

(Input) The information about the policy association to be removed. This field must contain information specific to the type of policy association you wish to remove. For example, for EIM_CERT_FILTER_POLICY (5) association type, the policyAssociation field must contain an EimCertificateFilterPolicyAssociation structure, for EIM_DEFAULT_REG_POLICY (6) association type, the policyAssociation field must contain an EimDefaultRegistryPolicyAssociation structure, and for EIM_DEFAULT_DOMAIN_POLICY (7) association type, the policyAssociation field must contain an EimDefaultDomainPolicyAssociation structure. The structure layouts follow:

```c
enum EimAssociationType {
    EIM_ALL_ASSOC,                  /* Not supported on this interface*/
    EIM_TARGET,                     /* Not supported on this interface*/
    EIM_SOURCE,                     /* Not supported on this interface*/
    EIM_SOURCE_AND_TARGET,          /* Not supported on this interface*/
    EIM_ADMIN,                      /* Not supported on this interface*/
    EIM_ALL_POLICY_ASSOC,           /* Not supported on this interface*/
    EIM_CERT_FILTER_POLICY,         /* Association is a certificate
                                     filter policy association. */
    EIM_DEFAULT_REG_POLICY,         /* Association is a default
                                     registry policy association */
    EIM_DEFAULT_DOMAIN_POLICY       /* Policy is a default policy for
                                     the domain. */
};

typedef struct EimCertificateFilterPolicyAssociation {
    char * sourceRegistry;          /* The source registry to remove
                                     the policy association from. */
    char * filterValue;             /* The filter value of the policy. */
    char * targetRegistry;          /* The name of the target registry
                                     that the filter value is mapped to. */
    char * targetRegistryUserName;  /* The name of the target registry
                                     user name that the filter value
                                     is mapped to. */
} EimCertificateFilterPolicyAssociation;

typedef struct EimDefaultRegistryPolicyAssociation
```
### eimRemovePolicyAssociation

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

#### Related Information

See the following:

- “eimAddPolicyAssociation” on page 181
- “eimListRegistryAssociations” on page 309

#### Authorization

**EIM data**

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator
- EIM registries administrator
- EIM authority to an individual registry. This authority is needed to the target registry.

**z/OS authorization**

No special authorization is needed.

#### Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
<th>MessageCatalogMessageID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
<td></td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>
<td>EIMERR_ACCESS (1)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Insufficient access to EIM data.</td>
</tr>
<tr>
<td>EBADDATA</td>
<td>eimrc is not valid.</td>
<td></td>
</tr>
<tr>
<td>Return Value</td>
<td>Meaning</td>
<td></td>
</tr>
<tr>
<td>-------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td>EBADNAME</td>
<td>Registry not found or insufficient access to EIM data.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_NOREG (28)</td>
<td>EIM registry not found or insufficient access to EIM data.</td>
<td></td>
</tr>
<tr>
<td>EBUSY</td>
<td>Unable to allocate internal system object.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_NOLOCK (26)</td>
<td>(z/OS does not return this value.) Unable to allocate internal system object.</td>
<td></td>
</tr>
<tr>
<td>ECONVERT</td>
<td>Data conversion error.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_DATA_CONVERSION (13)</td>
<td>(z/OS does not return this value.) Error occurred when converting data between code pages.</td>
<td></td>
</tr>
<tr>
<td>EINVAL</td>
<td>Input parameter was not valid.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_ASSOC_TYPE_INVAL (4)</td>
<td>Association type is not valid.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_FUNCTION_NOT_SUPPORTED (70)</td>
<td>The specified or configured EIM Domain controller does not support this API.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_HANDLE_INVAL (17)</td>
<td>EimHandle is not valid.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_PARM_REQ (34)</td>
<td>Missing required parameter. Please check the API documentation.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_PTR_INVAL (35)</td>
<td>(z/OS does not return this value.) Pointer parameter is not valid.</td>
<td></td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Unable to allocate required space.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_NOMEM (27)</td>
<td>No memory available. Unable to allocate required space.</td>
<td></td>
</tr>
<tr>
<td>ENOTCONN</td>
<td>LDAP connection has not been made.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_NOT_CONN (31)</td>
<td>Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.</td>
<td></td>
</tr>
<tr>
<td>EROFS</td>
<td>LDAP connection is for read-only. Need to connect to master.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_READ_ONLY (36)</td>
<td>This LDAP connection has &quot;read-only&quot; access. A connection to the master LDAP server with read/write is required to complete this operation. Use eimConnectToMaster to get a write connection or use the URL for the master EIM domain controller which is writeable..</td>
<td></td>
</tr>
<tr>
<td>EUNKNOWN</td>
<td>Unexpected exception.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_LDAP_ERR (23)</td>
<td>Unexpected LDAP error.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_UNKNOWN (44)</td>
<td>Unknown error or unknown system state.</td>
<td></td>
</tr>
<tr>
<td>EIMERR_UNEXP_OBJ_VIOLATION (56)</td>
<td>Unexpected object violation.</td>
<td></td>
</tr>
</tbody>
</table>
Example

```c
#include <eim.h>
#include <string.h>

int                      rc;
char                     eimerr[250];
EimRC                  * err;
EimHandle                handle;
EimPolicyAssociationInfo assocInfo;

/* Set up error structure. */
memset(eimerr,0x00,250);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 250;

/* Set up policy association information */
assocInfo.type = EIM_DEFAULT_REG_POLICY;
assocInfo.policyAssociation.defaultRegistry.sourceRegistry = "MySourceRegistry";
assocInfo.policyAssociation.defaultRegistry.targetRegistry = "localRegistry";
assocInfo.policyAssociation.defaultRegistry.targetRegistryUserName = "mjjones";

/* Remove the policy */
rc = eimRemovePolicyAssociation(&handle, &assocInfo, err);
```

eimRemovePolicyFilter

**Purpose**

Removes the specified policy filter from the domain. When a policy filter is removed, all policy associations to the policy filter are also removed.

**Format**

```c
#include <eim.h>
int eimRemovePolicyFilter(EimHandle            *eim,
                           EimPolicyFilterInfo  *filterInfo,
                           EimRC                *eimrc)
```

**Parameters**

*eim*

(Input) The EIM handle returned by a previous call to eimCreateHandle. A valid connection is required for this function.

*filterInfo*

The information about the policy filter to be removed. The structure layout follows:

```c
eum EimPolicyFilterType {
   EIM_ALL_FILTERS, /* All policy filters -- not supported for this interface. */
   EIM_CERTIFICATE_FILTER /* Policy filter is a certificate filter. */
};
typedef struct EimCertificatePolicyFilter {
   char  *sourceRegistry; /* The source registry to remove the policy filters from. */
   char  *filterValue;    /* The policy filter value. A NULL value will remove all policy filter values from the registry*/
} EimCertificatePolicyFilter;
typedef struct EimPolicyFilterInfo
```
enum EimPolicyFilterType type;
union {
    EimCertificatePolicyFilter certFilter;
} filter;
} EimPolicyFilterInfo;

**eimrc**

(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

See the following:

- “eimAddPolicyFilter” on page 185
- “eimListPolicyFilters” on page 293

**Authorization**

**EIM data**

EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:

- EIM administrator

**z/OS authorization**

No special authorization is needed.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the `messageCatalogMessageID` field in the `eimrc` parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>

<tr>
<td>EIMERR_NOT_CONN (31)</td>
<td>Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.</td>
</tr>
<tr>
<td>EROFS</td>
<td>LDAP connection is for read-only. Need to connect to master. Use eimConnectToMaster API to get a write connection or use the URL for the master EIM domain controller which is writeable.</td>
</tr>
<tr>
<td>EIMERR_READ_ONLY (36)</td>
<td>This LDAP connection has “read-only” access. A connection to the master LDAP server with read/write is required to complete this operation. Use eimConnectToMaster to get a write connection.</td>
</tr>
<tr>
<td>EUNKNOWN</td>
<td>Unexpected exception.</td>
</tr>
<tr>
<td>EIMERR_LDAP_ERR (23)</td>
<td>Unexpected LDAP error.</td>
</tr>
<tr>
<td>EIMERR_UNKNOWN (44)</td>
<td>Unknown error or unknown system state.</td>
</tr>
<tr>
<td>EIMERR_UNEXP_OBJ_VIOLATION (56)</td>
<td>Unexpected object violation.</td>
</tr>
</tbody>
</table>

### Example

```c
#include <eim.h>
#include <string.h>

int                 rc;
char                eimerr[250];
EimRC             * err;
EimHandle           handle;
EimPolicyFilterInfo filterInfo;

/* Set up error structure. */
memset(eimerr,0x00,250);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 250;
```
/** Set up policy information                           */
filterInfo.type = EIM_CERTIFICATE_FILTER;
filterInfo.filter.certFilter.sourceRegistry = "MySourceRegistry";
filterInfo.filter.certFilter.filterValue = NULL;

/* Remove the policy filter                        */
rc = eimRemovePolicyFilter(&handle, &filterInfo, err);

---

## eimRemoveRegistry

### Purpose
Removes a currently participating registry from the EIM domain.

### Note:
1. You cannot remove a system registry if there are any application registries that are a subset of the system registry.
2. When a registry is removed, an attempt is made to remove all associations for the registry. For policy associations, this includes all policy associations where this registry is either the source registry or the target registry. If there are any policy filters defined for the registry, the policy filters are removed along with any associations to the policy filters.

### Format

```c
#include <eim.h>

int eimRemoveRegistry(EimHandle *eim, char *registryName, EimRC *eimrc)
```

### Parameters

- **eim**
  (Input) The EIM handle that a previous call to eimCreateHandle returns. A valid connection is required.

- **registryName**
  (Input) The name of the registry to remove. Registry names are case-independent (meaning, not case-sensitive).
  
  The following special characters are not allowed in registry names:

  - , = + < > # ; \ *

- **eimrc**
  (Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

### Related Information

See the following:

- “eimAddApplicationRegistry” on page 170
- “eimAddSystemRegistry” on page 188
Authorization

EIM data
EIM access groups control access to EIM data. LDAP administrators also have access to EIM data. The access groups whose members have authority to the EIM data for this API follow:
- EIM administrator

z/OS authorization
No special authorization is needed.

Return Values
The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the eimrc parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data. <strong>EIMERR_ACCESS (1)</strong> Insufficient access to EIM data.</td>
</tr>
<tr>
<td>EBADDATA</td>
<td>eimrc is not valid.</td>
</tr>
<tr>
<td>EBADNAME</td>
<td>Registry not found or insufficient access to EIM data. <strong>EIMERR_NOREG (28)</strong> EIM registry not found or insufficient access to EIM data.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>Unable to allocate internal system object. <strong>EIMERR_NOLOCK (26)</strong> (z/OS does not return this value.) Unable to allocate internal system object.</td>
</tr>
<tr>
<td>ECONVERT</td>
<td>Data conversion error. <strong>EIMERR_DATA_CONVERSION (13)</strong> (z/OS does not return this value.) Error occurred when converting data between code pages.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Input parameter was not valid. <strong>EIMERR_HANDLE_INVAL (17)</strong> EimHandle is not valid. <strong>EIMERR_PARM_REQ (34)</strong> Missing required parameter. Please check the API documentation. <strong>EIMERR_PTR_INVAL (35)</strong> (z/OS does not return this value.) Pointer parameter is not valid.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Unable to allocate required space. <strong>EIMERR_NOMEM (27)</strong> No memory available. Unable to allocate required space.</td>
</tr>
<tr>
<td>ENOTCONN</td>
<td>LDAP connection has not been made. <strong>EIMERR_NOT_CONN (31)</strong> Not connected to LDAP. Use either the eimConnect or eimConnectToMaster API and try the request again.</td>
</tr>
<tr>
<td>Return Value</td>
<td>Meaning</td>
</tr>
<tr>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td>ENOTSAFE</td>
<td>Cannot delete a system registry when an application registry has this system registry defined.</td>
</tr>
</tbody>
</table>
|             | **EIMERR_REG_NOTEMPTY (40)**  
|             | Cannot delete a system registry when there is an application registry defined for this system registry. |
| EROFS       | LDAP connection is for read-only. Need to connect to master. Use the eimConnectToMaster API to get a write connection or use the URL for the master EIM domain controller which is writable. |
|             | **EIMERR_READ_ONLY (36)**  
|             | This LDAP connection has "read-only" access. A connection to the master LDAP server with read/write is required to complete this operation. Use eimConnectToMaster to get a write connection. |
| EUUNKNOWN   | Unexpected exception. |
|             | **EIMERR_LDAP_ERR (23)**  
|             | Unexpected LDAP error. |
|             | **EIMERR_UNEXP_OBJ_VIOLATION (56)**  
|             | Unexpected object violation. |
|             | **EIMERR_UNKNOWN (44)**  
|             | Unknown error or unknown system state. |

**Example**

The following example illustrates removing an EIM registry:

```c
#include <eim.h>

int           rc;
char          eimerr[200];
EimRC       * err;
EimHandle     handle;

/* Set up error structure. */
memset(eimerr,0x00,200);
err = (EimRC *)eimerr;
err->memoryProvidedByCaller = 200;

/* Remove the registry */
rc = eimRemoveRegistry(&handle, "MyRegistry", err);
```

**eimRetrieveConfiguration**

**Purpose**

This API retrieves the EIM configuration information for the specified or configured profile. Although similar to other &eserver_logo; platform implementations, the z/OS implementation does differ in the number of parameters passed to the API, and where and how configuration information is stored and retrieved.
#include <eim.h>

int eimRetrieveConfiguration(unsigned int lengthOfEimConfig,
   EimConfig * configData,
   char * profile,
   char * userIdentity,
   int ccsid,
   EimRC * eimrc)

Parameters

lengthOfEimConfig  
(Input) The number of bytes the caller provides for the configuration information. The minimum size required is 36 bytes.

configData  
(Output) A pointer to the data to return. The EimConfig structure contains information about the returned data. The API returns as much data as space has been provided. The EimConfig structure follows:

```c
typedef struct EimConfig
{
    unsigned int bytesReturned;     /* Number of bytes actually returned by the API. */
    unsigned int bytesAvailable;    /* Number of bytes of available data that could have been returned by the API. */
    int enable;                      /* Flag to indicate if enabled to participate in EIM domain
                                     0 = not enabled
                                     1 = enabled */
    EimListData ldapURL;            /* ldap URL for domain controller */
    EimListData localRegistry;      /* Local system registry */
    EimListData kerberosRegistry;   /* Kerberos registry */
    EimListData x509Registry;       /* X.509 registry */
    EimListData profileName;        /* The name of the profile storing the ldapURL and connect info */
    EimListData profClass;          /* The class of the profile */
    EimListData profBindDn;         /* The configured bind dn */
    EimListData profBindPw;         /* The configured bind password */
} EimConfig;
```

Note: The actual value of the bind password is not returned by this API. If the bind password is not set in the profile, the length of the profBindPw returned will be zero. If set, the value returned will be YES.

profile  
(Input) The name of a profile containing EIM configuration information for z/OS. The maximum size for this name is 246 bytes. Possible values are:

**NULL**

**a profile name**

The unique name of a profile in the LDAPBIND class, the IRR.EIM.DEFAULTS profile in the LDAPBIND class, or the IRR.PROXY.DEFAULTS profile in the FACILITY class.
When profile and userIdentity are both NULL, the API uses the search order for finding EIM configuration information on z/OS. The search order is:

- The LDAPBIND class profile associated with the caller's user ID
- The IRR.EIM.DEFAULTS LDAPBIND class profile
- The IRR.PROXY.DEFAULTS FACILITY class profile

Otherwise, the information is retrieved from the specified profile. Note that if userIdentity is specified at the same time as the profile parameter, an error is returned since you can specify either profile or userIdentity, neither, but not both.

**userIdentity**
(Input) The user identity with an associated LDAPBIND class profile. The maximum size of this user ID is 8 bytes. Possible values are:

- **NULL**
  a user identity
  The unique name of a user identity associated with an LDAPBIND class profile.

When profile and userIdentity are both NULL, the API uses the search order for finding EIM configuration information on z/OS. The search order is:

- The LDAPBIND class profile associated with the caller's user identity
- The IRR.EIM.DEFAULTS LDAPBIND class profile
- The IRR.PROXY.DEFAULTS FACILITY class profile

Otherwise, the domain and bind credentials are retrieved from the LDAPBIND class profile associated with the user identity.

The profile parameter must be NULL when userIdentity is used.

**ccsid**
(Input) The coded character set identifier (CCSID) for the output data. This parameter is ignored.

**eimrc**
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**

See the following:

- “eimSetConfiguration” on page 355

**Authorization**

**z/OS authorization**

The user identity associated with the application must have one of the following RACF authorities:

- SPECIAL
- CLAUTH authority to the FACILITY and LDAPBIND classes with field-level access checking set up for the fields in the PROXY and EIM segments of both classes.

See the *RACF System Administrator’s Guide* for details on how to grant user identities these authorities.

The calling application can be running in system key or supervisor state or one of the following:

- The RACF user ID of the caller’s address space has READ authority to the BPX.SERVER profile in the FACILITY class
- The current RACF user ID has READ authority to the IRR.RGETINFO.EIM profile in the FACILITY class
The FACILITY class must be active and RACLISTed before unauthorized (problem program state and keys) will be granted the authority to use this SAF service.

**Return Values**

The following table lists the return values from the API. Following each return value is the list of possible values for the messageCatalogMessageID field in the **eimrc** parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>

### Example

The following example retrieves the configuration information and prints out the results.

```c
#include <eim.h>
#include <stddef.h>
#include <stdio.h>
#include <string.h>

void printErr(EimRC *err);
void printListData(char * fieldName,
                   void * entry,
                   int offset);

int main (int argc, char *argv[])
{
    int           rc;
    char          eimerr[250];
    EimRC       * err;
    char          listData[4000];
    EimConfig   * list = (EimConfig *)listData;
    EimListData * pwData;
    int           pwLen;

    /* Set up error structure. */
    memset(eimerr,0x00,250);
    err = (EimRC *)eimerr;
    err->memoryProvidedByCaller = 250;

    /* Get configuration information using the default */
    /* search order. */
    /* (NULL userIdentity and profile parameter) */
    if (0 != (rc = eimRetrieveConfiguration(4000,
                                          list,
                                          NULL,
                                          NULL,
                                          0,0,
                                          0,0,0)) || 0 == rc)
```
{ /* Return RC and MSID to pinpoint any errors. */
    printf("Retrieve configuration RC = %d, MSID = %d\n", rc, err->messageCatalogMessageID);
    printErr(err);
    return -1;
}

/* Print the results */
printf("\n");
printf(" bytesReturned = %d\n", list->bytesReturned);
printf(" bytesAvailable = %d\n", list->bytesAvailable);
printf("\n");
if (0 == list->enable)
    printf("Profile is Disabled.\n");
else
    printf("Profile is Enabled.\n");

printListData("Profile Name", list,
    offsetof(EimConfig, profileName));
printListData("Profile Class", list,
    offsetof(EimConfig, profClass));
printListData("ldap URL", list,
    offsetof(EimConfig, ldapURL));
printListData("local Registry", list,
    offsetof(EimConfig, localRegistry));
printListData("kerberos registry", list,
    offsetof(EimConfig, kerberosRegistry));
printListData("x.509 registry", list,
    offsetof(EimConfig, x509Registry));
printListData("Bind distinguished name", list,
    offsetof(EimConfig, profBindDn));

pwData = (EimListData *)((char *)list + offsetof(EimConfig, profBindPw));
pwLen  = pwData->length;
if (pwLen > 0) {
    printf(" The Bind password is set\n");
} else {
    printf(" The Bind password is NOT set\n");
}
return 0;
}

void printListData(char * fieldName,
    void * entry,
    int offset)
{
    EimListData * listData;
    char    * data;
    int       dataLength;
    printf(" %s = ", fieldName);
    /* Address the EimListData object */
    listData = (EimListData *)((char *)entry + offset);
    /* Print out results */
    data = (char *)entry + listData->disp;
    dataLength = listData->length;
    if (dataLength > 0)
        printf("%.s\n", dataLength, data);
    else
        printf("Not found.\n");
}

/* Prints out the error message associated with the EimRC err structure. */
void printErr(EimRC *err)
{
eimSetAttribute

Purpose
Sets attributes in the EIM handle structure.

Format

```c
#include <eim.h>

int eimSetAttribute(EimHandle *eim, 
                     enum EimHandleAttr attrName, 
                     void *attrValue, 
                     EimRC *eimrc)
```

Parameters

eim
(Input) The EIM handle that a previous call to eimCreateHandle returns.

attrName
(Input) The name of the attribute to set. This can be:

- **EIM_HANDLE_CCSID (0)**
  (z/OS does not support this value.) This is the CCSID of character data that the caller of the EIM APIs passes by using the specified EIM handle. This field is a 4-byte integer. When a handle is created, this is set to the job default CCSID.

attrValue
(Input) A pointer to the attribute value.

eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see "EimRC -- EIM return code parameter for C/C++" on page 166.

Related Information

See the following:

- “eimConnect” on page 210
- “eimConnectToMaster” on page 214
- “eimCreateHandle” on page 223
- “eimDestroyHandle” on page 231
- “eimGetAttribute” on page 249

Authorization

**z/OS authorization**

No special authorization is needed.
Return Values

The following table lists the return values from the API. Following each return value is the list of possible values for the `messageCatalogMessageID` field in the `eimrc` parameter for that value.

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was successful.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>

</tr>
<tr>
<td></td>
<td><strong>EIMERR_ATTR_NOTSUPP (6)</strong></td>
</tr>
<tr>
<td></td>
<td>The specified attribute is not supported.</td>
</tr>
</tbody>
</table>

**eimSetConfiguration**

**Purpose**

This API sets configuration information for use with EIM. On z/OS, this API is not supported and simply returns an error indicating so. To set up EIM configuration information on z/OS, user either RACF commands or callable services or the `eimSetConfigurationExt` API.

**Format**

```c
#include <eim.h>

int eimSetConfiguration(int enable,
                         char * ldapURL,
                         char * localRegistry,
                         char * kerberosRegistry,
                         int ccsid,
                         EimRC * eimrc)
```

**Parameters**

**enable**

(Input) Indicates if this system is able to establish new connections in order to participate in an EIM domain. Possible values are:

- **0**
  - Not enabled to participate in EIM domain. You cannot establish new connections with the configured EIM domain.

- **non-zero**
  - Enabled to participate in EIM domain. You can establish new connections with the EIM domain.

**ldapURL**

(Input) A uniform resource locator (URL) that contains the EIM configuration information for the EIM domain controller. This information is used for all EIM operations. The maximum size for this URL is 1000 bytes. Possible values are:

- **NULL**
  - A value of NULL indicates that the LDAP URL that the system stores should not change.

- **EIM_CONFIG_NONE**
  - (*NONE) This value indicates that this system is not configured for EIM.
**ldapURL**
A URL that contains EIM domain controller information. This URL has one of the following formats:

```
ldap://host:port/dn
```

**host:port**
Is the name of the host on which the EIM domain controller is running. (The port number is optional.)

**dn**
Is the distinguished name for the domain entry.

**Example:**
```
ldap://systemx:389/ibm-eimDomainName=myEimDomain,o=myCompany,c=us
ldaps://systemy:636/ibm-eimDomainName=thisEimDomain,o=myCompany,c=us
```

**Note:** In contrast with `ldap`, `ldaps` indicates that this host and port combination uses SSL and TLS.

**localRegistry**
(Input) The local EIM system registry name. The maximum size for this registry name is 256 bytes. Possible values are:

- **NULL**
  A value of NULL indicates that the local registry name that the system stores should not change.

- **EIM_CONFIG_NONE**
  (*NONE) This value indicates that there is no local system registry.

**registry**
The local EIM system registry name.

**kerberosRegistry**
(Input) The EIM Kerberos registry name. The maximum size for this registry name is 256 bytes. Possible values are:

- **NULL**
  A value of NULL indicates that the EIM Kerberos registry that the system stores should not change.

- **EIM_CONFIG_NONE**
  (*NONE) This value indicates that there is no Kerberos registry for EIM.

**registry**
The EIM Kerberos registry name. This is the Kerberos realm name.

**ccsid**
(Input) The CCSID of the input data. If the `ccsid` is 0 or 65535, EIM uses the default job CCSID.

**eimrc**
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM sets eimrc with additional information. This parameter can be NULL. For the format of the structure, see “EimRC -- EIM return code parameter for C/C++” on page 166.

**Related Information**
None.

**Authorization**
No special authorization is needed.

**Return Values**
The following table lists the return values from the API. Following each return value is the list of possible values for the `messageCatalogMessageID` field in the `eimrc` parameter for that value.
### Return Value

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Access denied. Not enough permissions to access data.</td>
</tr>
<tr>
<td>ENOTSUP</td>
<td>Operation is not supported.</td>
</tr>
</tbody>
</table>

**EIMERR_API_NOTSUPP (6012)**

The EIM API not supported.

---

### eimSetConfigurationExt

**Purpose**

Sets the configuration information for use by the system. This information is stored in profiles and retrieved by other EIM APIs, allowing an application to manage the default domain, bind credentials, and registry names for use by the system, servers, or administrative users from an EIM administration application instead of using SAF services and TSO commands. If the profiles don't exist they will be created and can be deleted if requested.

With this API, you can do the following:

- Create, update, or delete a profile that represents the default domain and bind credentials for the system. You can use the following profiles:
  - the IRR.EIM.DEFAULTS profile in the LDAPBIND class. This is the preferred profile to use.
  - the IRR.PROXY.DEFAULTS profile in the FACILITY class. If you are already using policy director and the EIM domain is stored in the same LDAP directory, then this profile can be used when policy director and EIM use the same bind information.
- Create, update, delete, or list a profile that represents the default domain and bind credentials used by a server or EIM administrator. The profile is in the LDAPBIND class. The API also allows you to associate the profile with the server's or administrator's user ID.
- Store the registry names used in the EIM domain for the local registry, the kerberos registry, or the x.509 registry in the IRR.PROXY.DEFAULTS profile. The registry names are not used by EIM applications until they are brought into storage.

**Format**

```c
#include <eim.h>
int eimSetConfigurationExt(EimConfigInfo *configInfo, EimRC *eimrc);
```

**Parameters**

- `configInfo`
  
  The configuration information to be set. The structure layout follows:

  ```c
enum EimConfigFormat {
    EIM_CONFIG_FORMAT_0, /* Information is in configuration format 0. */
    ...
  };

typedef struct EimConfigFormat0 {
    char *ldapURL;       /* URL for EIM domain controller. */
    char *localRegistry; /* Local system registry name. */
    char *kerberosRegistry; /* Kerberos registry name. */
    char *x509Registry;  /* X.509 registry name. */
    char *profile;       /* Profile with EIM config info */
    char *userIdentity;  /* User id */
    char *bindDn;        /* Bind distinguished name */
    char *bindPw;        /* Bind password */
} EimConfigFormat0;

typedef struct EimConfigInfo
```
Details of the configuration information:

ldapURL
A uniform resource locator (URL) that contains the EIM configuration information for the EIM domain controller. This information will be used for all EIM operations. The maximum size for this URL on z/OS is 1024 bytes.

Possible values are:

NULL
Indicates a status that will not change.

EIM_CONFIG_NONE
(*NONE) This value indicates that this system is not configured for EIM.

ldapURL
A URL that contains EIM domain controller information.

The ldapURL has the following format: ldap://host:port/dn or ldaps://host:port/dn. Where:

host:port
The name of the host on which the EIM domain controller is running with an optional port number.

dn
The distinguished name for the domain entry.

ldap
Indicates that this host/port combination uses SSL and TLS.

Example:

ldap://systemx:389/ibm-eimDomainName=myEimDomain,o=myCompany,c=us
ldaps://systemy:636/ibm-eimDomainName=thisEimDomain

The URL is broken down into components and stored in the EIM profile. Specifying *NONE for this parameter means data in the LDAPHOST field of the PROXY segment and the DOMAINDN field in the EIM segment will be deleted. If the function specified is delete EIM profile (1), this parameter is ignored.

localRegistry
The local EIM system registry name. The maximum size for this name varies by platform, but is 255 bytes on z/OS. The possible values are:

NULL
Indicates a value which should not change.

EIM_CONFIG_NONE
(*NONE) This value indicates that there is no local system registry.

registry
The local EIM system registry name.
The registry name is always stored in the EIM segment of the IRR.PROXY.DEFAULTS profile in the FACILITY class. This parameter is ignored when the function is delete EIM profile (1).

**kerberosRegistry**
The EIM Kerberos registry name. The maximum size for this name is 256 bytes. The possible values are:

- **NULL**
  A value which should not change.
- **EIM_CONFIG_NONE**
  (*NONE) This value indicates that there is no kerberos registry for EIM.

**registry**
The EIM Kerberos registry name.

The registry name is always stored in the EIM segment of the IRR.PROXY.DEFAULTS profile in the FACILITY class. This parameter is ignored when the function is delete EIM profile (1).

**x509Registry**
The EIM X.509 registry name. The maximum size for this name varies by platform but is 255 bytes for z/OS. The possible values are:

- **NULL**
  A value which should not change.
- **EIM_CONFIG_NONE**
  (*NONE) This value indicates that there indicates that there is no X.509 registry for EIM.

**function**
The action to be performed on the profile. Possible values are:

- **EIM_CONFIG_FUNC_ADDMOD(0)**
  Create or update the profile containing EIM configuration data.
- **EIM_CONFIG_FUNC_DEL(1)**
  Delete the profile containing EIM configuration data.

**profile**
The name of a profile containing EIM configuration data. The maximum size is 246 bytes. Possible values are:

- **NULL**
  A value which should not change.
- **EIM_CONFIG_NONE**
  (*NONE) This value indicates that association of the LDAPBIND class profile with the userIdentity should be broken.

**system default profile**
- IRR.EIM.DEFAULTS profile in the LDAPBIND class or IRR.PROXY.DEFAULTS profile in the FACILITY class

**server or administrative user's profile**
a profile in the LDAPBIND class

**Note:**

1. If a profile name is specified without a user identity, the profile is created and updated as requested.
2. When a profile name is specified with a user identity and the profile is something other than IRR.EIM.DEFAULTS or IRR.PROXY.DEFAULTS, the profile is created if it doesn't exist, and associated the specified user identity.
3. When EIM_CONFIG_NONE (*NONE) is used for the profile name and a user identity is specified, the association the user identity may have with an LDAPBIND class profile is broken. All other parameters are ignored in this case.

**userIdentity**
The user ID associated with an LDAPBIND class profile. The maximum size for this user ID is 8 bytes. Possible values are:

- **NULL**
  Indicates a value which will not change.

**user identity**
The specific user identity you wish to associate with the LDAPBIND class profile. Possible values are:

- NULL
- a user identity

**bindDn**
The bind distinguished name that is stored in the profile. The bind distinguished name is the identity used when binding with LDAP. This parameter allows the information to be added, replaced, or removed from a profile. This parameter is ignored when the function is delete EIM profile (1). The maximum size for a bindDn varies by platform but is 1023 bytes.

The bindDn parameter may have one of the following values:

- **NULL**
  A value of NULL indicates that it should not change.
- **EIM_CONFIG_NONE**
  (*NONE) This value indicates that there is no bindDn.

**value**
The bindDn. This value is used when establishing a connection with the domain name stored in the profile.

**bindPw**
The bind password that is stored in the profile. The bind password is used when binding with LDAP. This parameter allows the information to be added, replaced, or removed from a profile. This parameter is ignored when the function is delete EIM profile (1). The maximum size for a bindPw varies by platform but is 128 bytes for z/OS.

The bindPw parameter may have one of the following values:

- **NULL**
  A value of NULL indicates that it should not change.
- **EIM_CONFIG_NONE**
  (*NONE) This value indicates that there is no bindPw.

**value**
The bindPw. This value is used when establishing a connection with the domain name stored in the profile.

This parameter is ignored when the profile name is IRR.EIM.DEFAULTS or IRR.PROXY.DEFAULTS.

**enable**
(Input) Indicates if this system is able to establish new connections in order to participate in an EIM domain. Possible values are:

- 0
  Not enabled to participate in EIM domain. New connections cannot be established with the configured EIM domain.

- non-zero
  Enabled to participate in EIM domain. New connections may be established with the EIM domain.

This parameter is ignored when the function is delete EIM profile (1).
ccsid
(Input) The CCSID of the input data. If the ccsid is 0 or 65535 the default job ccsid will be used. The
CCSID parameter is not used by all platforms. See the authorization section for specific details.

eimrc
(Input/Output) The structure in which to return error code information. If the return value is not 0, EIM
sets eimrc with additional information. This parameter can be NULL. For the format of the structure,
see “EimRC -- EIM return code parameter for C/C++” on page 166.

Related Information
See the following:
• “eimRetrieveConfiguration” on page 348

Authorization

EIM data
This API does not connect to the LDAP Server, so there is no EIM data being accessed. Therefore, no
EIM authority is needed.

z/OS authorization
The RACF user ID of the caller must satisfy the following requirements:
The calling application can be running in system key or supervisor state or one of the following:
• The RACF user ID of the caller’s address space has READ authority to the BPX.SERVER profile in the
  FACILITY class
• The current RACF user ID has READ authority to the IRR.RGETINFO.EIM profile in the FACILITY
  class

For applications that are not authorized (problem program state and keys), the current RACF user ID
must satisfy the following requirements:
• Have READ authority to the following profiles in the FACILITY class:
  – IRR.RADMIN.ALTUSER
  – IRR.RADMIN.RDEFINE
  – IRR.RADMIN.RALTER
  – IRR.RADMIN.RDELETE
• Have authority to issue the following commands:
  – ALTUSER
  – RALTER
  – RDEFINE
  – RDELETE

The FACILITY class must be active and RACLISTed before the application will be granted authority to
use this SAF service

Return Values
The following table lists the return values from the API. Following each return value is the list of possible
values for the messageCatalogMessageID field in the eimrc parameter for that value.

### Example

The following example sets the configuration information but it is not enabled.

```c
#include <eim.h>
#include <stdio.h>
#include <string.h>
#include <errno.h>

int main (int argc, char *argv[]) {
    int            rc;
    char           ldapURL[250];
    char           eimerr[1000];
    EimRC         * err;
    EimConfigInfo   configInfo;
    char          * errstr;

    err = (EimRC *)eimerr;
    memset(eimerr, 0x00, 1000);
    err->memoryProvidedByCaller = 1000;

    memset(&configInfo, 0x00, sizeof(EimConfigInfo));
    configInfo.format = EIM_CONFIG_FORMAT_0;
    configInfo.enable = 1;
    configInfo.function = EIM_CONFIG_FUNC_ADDMOD;
    configInfo.config.format0.ldapURL =
        "ldap://localhost:389/ibm-eimDomainName=MyDomain,o=MyOrg,c=us";
    configInfo.config.format0.profile = "timmys.ldapbind.profile";
    configInfo.config.format0.userIdentity = "timmy";
    configInfo.config.format0.localRegistry = "SYS1.RACFDB";
    configInfo.config.format0.kerberosRegistry = "z/OS KDC";
    configInfo.config.format0.x509Registry = "PKI Services";
```

364 z/OS: Integrated Security Services Enterprise Identity Mapping (EIM) Guide and Reference
configInfo.config.format0.bindDn = "cn=racfid=timmy,profiletype=user,o=racfdb,c=us";
configInfo.config.format0.bindPw = "secret";

if (eimSetConfigurationExt(&configInfo, err)) {
    if (NULL == (errstr = eimErr2String(err))) {
        printf("eimSetConfigurationExt failed; rc=(%d) msgid(%d) errno: %s\n",

    EimRC          * eimrc          /* Input/Output: return code      */
};                                                             /* @01A*/
int eimRemoveAccess
{   
    EimHandle      * eim,           /* Input: Eim handle              */
    EimAccessUser  * accessUser,    /* Input: User for access         */
    enum EimAccessType accessType,  /* Input: Type of access          */
    char           * registryName,  /* Input: Registry name           */
    EimRC          * eimrc          /* Input/Output: return code      */
};                                                             /* @01A*/
int eimListAccess
{   
    EimHandle      * eim,           /* Input: Eim handle              */
    enum EimAccessType accessType,  /* Input: Type of access          */
    char           * registryName,  /* Input: Registry name           */
    unsigned int lengthOfListData, /* Input: size provided for 
                                      listData */
    EimList  * listData,    /* Output: In EimList the field 
                               firstEntry will get to the 
                               first EimAccess element */
    EimRC    * eimrc       /* Input/Output: return code */
};                                                             /* @01A*/
int eimListUserAccess
Example for creating LDAP suffix and user objects

The following is a sample ldapadd command and ldif file to create suffix objects and an LDAP user object. Here are the suffix.ldif file contents:

```plaintext
# --------------------------------------------------------------------
# Create the country us object
# --------------------------------------------------------------------
dn: c=us
objectclass: top
objectclass: country
c: us

# --------------------------------------------------------------------
# Create the ibm organization under c=us
# --------------------------------------------------------------------
dn: o=ibm,c=us
objectclass: top
objectclass: organization
o: ibm

# --------------------------------------------------------------------
# Create the dept20 organizational unit object under
# o=ibm,c=us
# --------------------------------------------------------------------
dn: ou=dept20,o=ibm,c=us
objectclass: top
objectclass: organizationalunit
ou: dept20

# --------------------------------------------------------------------
# Create the eim administrator user object with a password
```

EimHandle * eim,  /* Input: Eim handle */
EimAccessUser * accessUser,  /* Input: User for access */
unsigned int lengthOfListData, /* Input: size provided for listData */
EimList * listData, /* Output: In EimList the field firstEntry will get to the first EimUserAccess element */
EimRC * eimrc /* Input/Output: return code */
);

int eimQueryAccess
(
  EimHandle * eim,  /* Input: Eim handle */
  EimAccessUser * accessUser, /* Input: User for access */
  enum EimAccessType accessType, /* Input: Type of access */
  char * registryName, /* Input: Registry name */
  unsigned int * accessIndicator, /* Output: Indicates whether access found */
  EimRC * eimrc /* Input/Output: return code */
);

/* --------------------------------------------------------------------
/* Error Message */
/* --------------------------------------------------------------------

char * eimErr2String
(
  EimRC * eimrc /* Input: return code */
);

#pragma enum(pop)
#endif __cplusplus
#endif /* _OS400_TGTVRM _>=510 */
#pragma datamodel(pop)
#endif /* EIM_h */
Then, to add these entries to LDAP, issue the following `ldapadd` command from the z/OS UNIX shell:

```bash
ldapadd
-h ldap://some.ldap.host
-D cn=ldap administrator
-w secret
-f suffix.ldif
```
Chapter 13. The z/OS Identity Cache

Today's transaction environments are typically multi-platform heterogeneous configurations with disparate security domains. Each security domain can have its own security service provider and authentication methods. While a user might be authenticated in one security domain, the authenticated identity information may be lost when transactions initiated in one security domain are executed in another.

For example, a user may authenticate his or her identity to a security product running in a distributed environment, and then initiate a transaction that executes on a z/OS system under the authority of a shared identity. Since the user's original authenticated identity is not known to z/OS, SMF audit records contain information only for the shared identity. Because the original authenticated identity is not maintained across the security domains, individual accountability is lost.

The z/OS Identity Cache enables an application to maintain identity information across security domains, so that individual accountability is not lost. Distributed applications can use the z/OS Identity Cache to enable end-to-end auditing that tracks the identity initially used for authentication as well as the identity on the current platform.

The primary interface to the z/OS Identity Cache is the ICTX Java API which enables applications to store identity context information in the Identity Cache on the local or on a remote z/OS system. Remote access to the Identity Cache from a z/OS or non-z/OS system is provided by LDAP extended operations support which is leveraged by the ICTX Java API. Cache management is provided by the R_cacheserv SAF callable service.

The ICTX Java API method for storing identity context information in the Identity Cache returns a reference which can subsequently be used to retrieve that information. For example, a distributed application could pass the reference to a RACF-secured z/OS application which could then retrieve the original user authentication information from the Identity Cache. In particular, the RACROUTE REQUEST = VERIFY macro and the initACEE SAF callable service both accept an identity context reference as a user ID and password and will create an accessor environment element (ACEE) that includes the identity context information from the Identity Cache. This information will in turn be included in SMF audit records.

How the z/OS Identity Cache works

An application can store user authentication information in the z/OS Identity Cache, and will get an 8-byte identity context reference value which can subsequently be used to retrieve that information. The reference can be passed to an application running on z/OS, so that when it uses the RACROUTE REQUEST=VERIFY macro or the initACEE service to create a z/OS security context, the ACEE created will be extended to include the original authentication information. Because the original authentication information is now included in the ACEE, SMF audit records for the user will also contain this extended authentication information.

The following figure illustrates how a distributed application can use the z/OS Identity Cache to make the original user authentication information available to a remote z/OS application and system.
In this figure, the user (1) authenticates to a distributed application. The distributed application uses the ICTX Java API to (2) store the authentication information in the z/OS Identity Cache on a remote z/OS system. The ICTX Java API (3) returns the identity context reference to the calling application, which in turn (4) passes this reference to a RACF-secured z/OS application. The z/OS application uses the identity context reference in place of a user ID and password, when it (5) calls the RACROUTE REQUEST=VERIFY macro or the initACEE SAF callable service to build the security context for the user. RACF will recognize that the supplied user ID and password is an identity context reference, and so will (6) retrieve the user authentication information from the z/OS Identity Cache and will build an ACEE that contains the extended authentication information for the user. This extended authentication information from the Identity Cache will be included in subsequent SMF audit records for transactions initiated by the user.

The application accessing a z/OS Identity Cache may be running locally or remotely. Remote applications running on either a z/OS or non-z/OS system can access an Identity Cache on a remote z/OS system using a z/OS IBM TDS server configured with ICTX extended operations. The application will provide the ICTX Java API with a URL identifying the z/OS IBM TDS server as well as the ID and password for a RACF user ID on the remote system. The z/OS IBM TDS server will perform a simple bind operation using the supplied RACF ID and password for authentication to the remote z/OS system. For z/OS applications accessing the local Identity Cache, the z/OS IBM TDS server is not needed.

The Identity Cache can be configured to ensure that the stored information on the authenticated user also contains a mapping to a local z/OS user ID. The Identity Cache can be configured to accept a mapping supplied by the application, or it can be configured to access an EIM domain to perform a lookup operation to find the mapping. The local user ID, whether provided by the application or identified using an EIM lookup operation, will be stored in the Identity Cache along with the initial authentication information. If a reference to an identity context in this Identity Cache is passed to the RACROUTE REQUEST=VERIFY macro or the initACEE SAF callable service, the resulting ACEE, and subsequent SMF audit records, will also include the additional mapped local user ID information.
Configuring your environment to use the z/OS Identity Cache

Some configuration is required for z/OS systems that host, and applications that use, an Identity Cache. The authenticating application needs to know where the Identity Cache is located so that it can store information about the end user and get back an identity context reference. The authenticating application then passes the identity context reference to a server which also needs to know where the Identity Cache resides so that it can retrieve the stored information. An application will need to know if it is accessing the Identity Cache on a local node, or if it accessing the Identity Cache on a remote node. If accessing the Identity Cache on a remote node, the application will need to know the host name of the z/OS IBM TDS server that is providing the connection to the remote system.

If you want the Identity Cache to contain user ID mappings from the authenticated user ID to a local z/OS user ID, you need to configure the Identity Cache to specify that ID mapping is required. You can also configure the Identity Cache to specify how it should obtain these mappings – from the application storing the authenticated user ID information in the Identity Cache, from an EIM lookup operation, or using a combination of these approaches. If the Identity Cache is configured to do an EIM lookup, an EIM domain will also need to be set up.

If you are using the Identity Cache on more than one system in a z/OS sysplex, there are some additional configuration considerations. See “Configuring z/OS sysplex for the Identity Cache” on page 397 for more information.

Configuring Java applications to use the z/OS Identity Cache

The main application interface to the z/OS Identity Cache is the ICTX Java API described in more detail in Chapter 14, “ICTX Java API,” on page 399. Applications can use the API to access the Identity Cache on the local z/OS system or on a remote z/OS system.

To use the ICTX Java API to access a z/OS Identity Cache on either the local or a remote z/OS system, all applications must:

- have access to the ICTX Java classes defined in the ictx.jar file, which is located in the /usr/lpp/eim/lib HFS directory. To get access to the ICTX Java classes, include the ictx.jar file in the CLASSPATH of the Java application.
- have a RACF user ID on the z/OS system where the Identity Cache is located, and the permission necessary to access the Identity Cache. The ICTX Java API uses the R_cacheserv callable service to perform read and write operations to the Identity Cache. Use of the R_cacheserv callable service is authorized by the IRR.RCACHESERV.ICTX resource in the FACILITY class, so the RACF user ID associated with the request to access the Identity Cache must have the correct access permission to the IRR.RCACHESERV.ICTX resource in the FACILITY class.
  - If the application is a z/OS application accessing the Identity Cache on the local system, then the RACF user ID associated with the request is the one under which the application is running.
  - If the application is running on a z/OS or non-z/OS system and accessing the Identity Cache on a remote z/OS system, it will be accessing the remote system's Identity Cache through an IBM TDS server. In this case, the RACF user ID associated with the request is the RACF user ID used to authenticate with the remote z/OS system through an LDAP bind operation.

The level of access permission required to access the IRR.RCACHESERV.ICTX resource in the FACILITY class depends on the specific type of operation the application needs to perform.

- If the application is going to store user information in the Identity Cache, then the RACF user ID needs UPDATE access to the IRR.RCACHESERV.ICTX resource in the FACILITY class.
- If the application is going to retrieve information from the Identity Cache (using either the ICTX Java API, the RACROUTE REQUEST=VERIFY macro, or the initACEE SAF callable service), then the RACF user ID needs READ access to the IRR.RCACHESERV.ICTX resource in the FACILITY class.

The FACILITY class must be active and enabled for RACLIST processing. Access updates for a user will not take effect until the user logs on again.
In addition to the preceding configuration requirements common to all Java applications, additional configuration requirements vary depending on whether the application is accessing the Identity Cache on the local or on a remote z/OS system.

- If the application will be accessing the Identity Cache on the local z/OS system, it must also have access to the EIM and ICTX API routines. To get access to these routines, include the HFS directory /usr/lpp/eim/lib in the LIBPATH of the z/OS Java application.

- If the application will be accessing the Identity Cache on a remote z/OS system, it must also specify:
  - the host name and, optionally, the port number for the z/OS IBM TDS server that is providing the connection to the z/OS Identity Cache on the remote system. This host name may begin with ldap:// or ldaps://. If ldaps:// is used, then it is assumed the IBM TDS server as been set up for SSL or TLS communication.
  - If the application is running on a z/OS system, the host name for the z/OS IBM TDS server can be set as an in-storage Identity Cache default value (as described in “Configuring Identity Cache connection defaults” on page 397).
  - If the application is running on a non-z/OS system, the host name for the z/OS IBM TDS server could be obtained from a properties file specific to the application.
  - the bind credentials for connecting to the remote system. The bind credentials correspond to a RACF user ID and password on the remote system. If the application is running on a z/OS system, the bind credentials can be set as in-storage Identity Cache default values (as described in “Configuring Identity Cache connection defaults” on page 397).

The z/OS IBM TDS server needs to have been configured with ICTX extended operations and started. To configure the z/OS IBM TDS server with ICTX extended operations, modify the ds.conf file with a section that defines the ICTX extended operations support. For more information, refer to “Configuring the IBM Tivoli Directory Server for remote services support” on page 399.

### Configuring the z/OS Identity Cache

You can configure the Identity Cache to:

- determine if, and how, mappings to local z/OS user IDs will be included in the Identity Cache. These user ID mappings can be provided by applications, or determined by an EIM lookup operation. The Identity Cache can be configured so that valid ID mappings are:
  - not stored, even if provided by applications
  - optionally stored if provided by an application or identified using EIM
  - required, so that the operation to store information in the Identity Cache will fail if a valid ID mapping is not provided by an application or identified using EIM.

An expiration time for stored mappings can also be configured.

- specify, for applications running on z/OS, defaults for connecting to the Identity Cache.

### Configuring user ID mapping

You can configure the Identity Cache to specify how mappings to local z/OS user IDs should be handled. These configuration options can be specified in the IRR.ICTX.DEFAULTS.sysid or IRR.ICTX.DEFAULTS profile in the LDAPBIND class.

- The USEMAP configuration option specifies whether to accept or ignore user ID mappings provided by applications. If you specify USEMAP(YES), and an application provides a valid mapping to a local z/OS user ID, it will be stored in the Identity Cache. If you specify USEMAP(NO), application-provided ID mappings will be ignored.
- The DOMAP configuration option specifies whether or not EIM services should be used to map a user ID stored by the application in the Identity Cache to a local z/OS user ID. If you specify DOMAP(YES), an EIM lookup operation will be used to find the ID mapping. If a mapping is found, it will be stored in the Identity Cache. If you specify DOMAP(NO), the Identity Cache will not use EIM to find a mapping.
If DOMAP(YES) is used, the Identity Cache needs to be fully configured to access the EIM domain. See “Configuring and setting up EIM” on page 396 for more information.

- The MAPREQUIRED configuration option specifies whether or not a mapping to a local z/OS user ID is required. If MAPREQUIRED(YES) is specified and no valid mapping is provided by the application or found using EIM, the application request to store information in the Identity Cache will fail. If MAPREQUIRED(NO) is specified, then valid ID mappings will, if provided by the application or found using EIM, be stored in the Identity Cache, but will not be required.

The following are the default user ID mapping settings:
- USEMAP(YES) — user ID mappings provided by applications are accepted
- DOMAP(NO) — the Identity Cache does not perform mapping itself
- MAPREQUIRED(NO) — there is no requirement for a user ID mapping to be stored with user information

The following table summarizes the combined effect of the various configuration option settings.

<table>
<thead>
<tr>
<th>USEMAP</th>
<th>DOMAP</th>
<th>MAPREQUIRED</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO</td>
<td>NO</td>
<td>NO</td>
<td>The Identity Cache will not use an application provided mapping to a z/OS user ID and it will not use EIM to find a mapping. Even if an application mapping is provided, no mapping is stored.</td>
</tr>
<tr>
<td>NO</td>
<td>NO</td>
<td>YES</td>
<td>The Identity Cache will not use an application provided mapping to a z/OS user ID and it will not use EIM to find a mapping. A mapping is required, so the Identity Cache will return an error.</td>
</tr>
<tr>
<td>NO</td>
<td>YES</td>
<td>NO</td>
<td>The Identity Cache will not use an application provided mapping to a z/OS user ID. It will use EIM to find a mapping. If a mapping is found, it will be stored. If no mapping is found, the Identity Cache will not return an error.</td>
</tr>
<tr>

</tr>
<tr>
<td>YES</td>
<td>YES</td>
<td>YES</td>
<td>If an application provides a mapping to a z/OS user ID, the Identity Cache will store it. If not, the Identity Cache will use EIM to find a mapping to store. If no mapping is provided or found, the Identity Cache will return an error.</td>
</tr>
</tbody>
</table>

Since user ID mappings can change over time, a user ID mapping stored in the Identity Cache will expire. By default, a user ID mapping will be stored in the Identity Cache for 1 hour, but you can set this to a shorter interval using the MAPPINGTIMEOUT configuration option. The MAPPINGTIMEOUT interval is specified in seconds, and valid values range from 1 to 3600.

A copy of the current configuration settings is kept in-storage to allow fast access to the values. The configuration settings can be defined in an IRR.ICTX.DEFAULTS.sysid profile in the LDAPBIND class. For example:

```plaintext
RDEFINE LDAPBIND IRR.ICTX.DEFAULTS.SYSA ICTX(USEMAP(NO) DOMAP(YES) MAPREQUIRED(YES) MAPPINGTIMEOUT(1800)) EIM(LOCALREGISTRY(MyZOSRegistry))
```

This example defines the settings for the system with a system ID of SYSA, and establishes the following rules:

- Because USEMAP(NO) is specified, any mappings provided by the application are ignored.
- Because DOMAP(YES) is specified, the Identity Cache itself will extract mappings from EIM. Because LOCALREGISTRY(MyZOSRegistry) is specified, the Identity Cache will use the EIM registry name of MyZOSRegistry when looking for mappings in the configured EIM domain.
- Because MAPREQUIRED(YES) is specified, any requests to store user identity information are rejected if a mapping can’t be found in EIM.
- Because MAPPINGTIMEOUT(1800) is specified, the mappings to RACF user IDs that are stored in the cache can be reused for 30 minutes instead of the default 1 hour.

These same values could be stored in a profile with the name IRR.ICTX.DEFAULTS. However, be careful using this because applications on other systems that are sharing the RACF database may also default to using this same profile.

The final step to making the settings take effect is that the LDAPBIND class must be active and RACLSTED. The entire set of field values must be specified or defaulted to in the profile before the in-storage copy of the fields is updated.

**Configuring and setting up EIM**

When the Identity Cache is configured to do an EIM lookup; an EIM domain needs to be set up. This domain is a directory on an IBM TDS server which contains EIM data for an enterprise, and is a collection of all EIM identifiers, associations, and user registries that are defined in that location. EIM clients participate in the domain by using the domain data for EIM lookup operations. In order for Identity Cache to do a lookup, the EIM domain must contain the required data for mapping a user identity defined remotely to a user identity defined locally. The IBM TDS server that hosts your EIM domain can run on a z/OS or non-z/OS system. See Part 1, “EIM concepts and use,” on page 1 for more information on how to set up your EIM domain.
Once you have set up your EIM domain, you will also need to use RACF commands to give the Identity Cache access to the EIM domain by defining the domain name, the distinguished name, and password which will be used for IBM TDS binding. See “Setting up default domain LDAP URL and binding information” on page 62 for more information about how to do this.

If you choose to create a profile for IBM TDS binding information, you will need to update the RACF user ID with this information. The user ID you will need to update depends on whether the request is local or remote. If the request is remote, you will need to update the user ID used in the LDAP bind operation. If the request is local, you will need to update the user ID under which the application is running. For example, to update the RACF user ID IBMUSER, you would use the following command:

```
ALU IBMUSER EIM(LDAPPROF("+ racfProfile +"))
```

**Configuring Identity Cache connection defaults**

Applications running on z/OS and using the Identity Cache may choose to use the configured Identity Cache for that system. That cache can reside on another z/OS box or on the local z/OS system. To access a cache running on a remote system, the command that would need to be issued is:

```
RDEFINE LDAPBIND IRR.ICTX.DEFAULTS.sysid PROXY(LDAPHOST(hostname) BINDDN("racfid=userid,cn=ictx") BINDPW(password))
```

The LDAPBIND class needs to be active and RACLISTed so that the LDAPHOST name is stored in the in-storage copy of the values.

The application's RACF user ID also requires READ access to the IRR.RDCEKEY profile in the FACILITY class, so that the Identity Cache can retrieve remote configuration information from RACF.

To get better performance where possible, add the APPLDATA field to the ICTX defaults profile. It should contain the IBM TDS host name given to the local Identity Cache.

**Configuring z/OS sysplex for the Identity Cache**

If using the Identity Cache on more than one system in a z/OS sysplex, you must ensure that RACF is enabled for sysplex communication and that the RACF database used by each member of the sysplex is synchronized. RACF recommends that all systems enabled for sysplex communication and sharing the same RACF database be members of the same sysplex. Doing this prepares you for RACF sysplex data sharing, and ensures that commands are propagated to all members of the sysplex.

For information on enabling RACF for sysplex communication, refer to z/OS Security Server RACF General User's Guide.
Chapter 14. ICTX Java API

The ICTX Java API is the primary interface for working with the z/OS Identity Cache. The z/OS Identity Cache (described in Chapter 13, “The z/OS Identity Cache,” on page 391) can be used by applications to communicate user authentication information across security domain boundaries. An application running on a z/OS or non-z/OS system can use the ICTX Java API to store identity context information in the Identity Cache on the local, or on a remote, z/OS system.

The ICTX Java API provides two logical sets of services – one for specifying and parsing authentication information, and one for storing that information in, and retrieving it from, the z/OS Identity Cache. These two logical sets of services are provided in three packages.

- The /com/ibm/ictx/authenticationcontext package contains interfaces and public classes for specifying and parsing user authentication information called an authentication context. The authenticating application uses the classes and methods provided in this package to build an authentication context for a user, and ultimately transforms it into an identity context object that can be stored into a z/OS Identity Cache. The terms authentication context and identity context are largely synonymous; the difference is that an identity context is just an array of bytes that can be stored in, and retrieved from, the z/OS Identity Cache. The authenticating application specifies the authentication context information using the various classes in this package, and then builds the identity context so that information can be stored in the z/OS Identity Cache. The application that retrieves the identity context can use the classes and methods of this class to parse the identity context for the authentication context information supplied by the authenticating application.

- The /com/ibm/ictx/identitycontext package contains interfaces and public classes for storing an identity context in, and retrieving an identity context from, the z/OS Identity Cache. Two storage mechanism classes are provided in this package for interacting with a z/OS Identity Cache. The LdapStorageMechanism class is designed for applications that will access a z/OS Identity Cache remotely using a z/OS IBM TDS server configured with ICTX extended operations, and the zOSStorageMechanism class is for applications that are accessing a z/OS Identity Cache locally. A special factory class (StorageMechanismFactory) for instantiating an object of the appropriate storage-mechanism class (based on the location of the executing code, certain configuration settings, and information supplied by the application) is also provided in this package.

- The /com/ibm/ictx/util package contains utility classes used by the classes in the other two packages. Classes are provided for representing an identity context and exceptions thrown by other classes.

The ICTX Java API is provided in the ctx.jar file, which is located in the /usr/lpp/eim/lib HFS directory.

The information provided here is only an overview of the ICTX Java API. While the interfaces and classes are listed, and the basic tasks an application can perform are summarized, detailed syntax information is not provided. For full details on the ICTX Java API, see the reference documentation provided in Javadoc format at z/OS downloads (www.ibm.com/systems/z/os/zos/downloads).

Configuring the IBM Tivoli Directory Server for remote services support

The ICTX Java APIs use an IBM Tivoli Directory Server client to send authentication information to the server. The ICTX extended operations support provides the database functions for this information. To enable this, the IBM TDS configuration file must have a section that identifies the ICTX extended operations support.

To enable ICTX extended operations support, do the following:
• create a new section in the IBM Tivoli Directory Server SLAPDCNF configuration file by adding the following lines:

```plaintext
# ICTX extended operations support section
plugin clientOperation ITYBIC31 ICTX_INIT "CN=ICTX"
```

This statement must appear before any database definitions within the file.

• You must ensure the EIM libraries can be located via the IBM TDS LIBPATH. Add the following LIBPATH environment variable:

```plaintext
LIBPATH=/usr/lib
```

This statement should appear in the file specified by the ENVVAR DD in the JCL for the IBM TDS started task.

## /com/ibm/ictx/authenticationcontext package

The `/com/ibm/ictx/authenticationcontext` package contains interfaces and public classes for specifying and parsing user authentication information. The authenticating application uses the classes and methods provided in this package to build an authentication context for a user, and ultimately transforms it into an IdentityContext object that can be stored into a z/OS Identity Cache. The application that retrieves the IdentityContext object can use the classes and methods of this class to parse the identity context for the information supplied by the authenticating application.

The following table lists the interfaces and classes provided in the `/com/ibm/ictx/authenticationcontext` package. For complete information on these interfaces and classes, refer to the ICTX Java API reference documentation provided in Javadoc format at z/OS downloads (www.ibm.com/systems/z/os/zos/downloads).

The classes and methods for interacting with the z/OS Identity Cache to store and retrieve an IdentityContext object are organized in the /com/ibm/ictx/identitycontext package, while the IdentityContext class is provided in the /com/ibm/ictx/util package. See “/com/ibm/ictx/identitycontext package” on page 406 and “/com/ibm/ictx/util package” on page 409 for more information.

Creating an identity context object from authentication context information

The following figure illustrates the classes and methods an application can use to specify authentication context information for a user, and, from that authentication context information, build an identity context object that can stored in the z/OS Identity Cache.

Use these objects...

- AuthenticationInfo object
- ApplicationInfo object representing sending application
- ApplicationInfo object representing receiving application (optional)
- PremappedUserInfo object (optional)

To construct...

BuildSpec1 object

Pass as argument to...

Type1AuthenticationManager object

buildIdentityContext method

Which returns...

IdentityContext object

To create an identity context, an application needs to:

1. construct the objects that will be passed as arguments when constructing a BuildSpec1 object. The objects that will be passed as arguments to the BuildSpec1 class constructor are:
   a. an AuthenticationInfo object (authInfo argument) representing user authentication information. At a minimum, the application provides the name of the user who was authenticated and the name of the user registry for the authenticated user. The application can also supply the DNS name of the host system where the user was authenticated, the mechanism used to authenticate the user, and the security label associated with this user. In addition, implementation-specific data can be provided.
b. an ApplicationInfo object (sndAppInfo argument) that represents the current application. At a minimum, the application provides its identifier name and an instance name that uniquely identifies it in the network. In addition, implementation-specific data can be provided.

c. optionally, another ApplicationInfo object (rcvAppInfo argument) — this one identifying the application that is the intended recipient of the identity context. The application might want to provide this information so that the receiving application can verify that it is the intended recipient.

d. optionally, a PremappedUserInfo object (premapped argument) that enables the application to provide a mapping from the local authenticated user ID to a z/OS user ID valid on the system hosting the z/OS Identity Cache. Whether such mappings are required, accepted but not required, or ignored by the z/OS Identity Cache depends on how the Identity Cache is configured. See “Configuring user ID mapping” on page 394 for more information.

2. construct a BuildSpec1 object, which represents the information required to build an authentication context object, from the objects you created in the preceding step. The application can specify the AuthenticationInfo object, the ApplicationInfo object(s) and the PremappedUserInfo object as arguments to the BuildSpec1 constructor. If the application is not specifying the intended application recipient for the identity context or is not providing a user ID mapping, a null value can be specified instead of the ApplicationInfo object or the PremappedUserInfo object.

When constructing the BuildSpec1 object, the application can also specify a timeout value representing the number of seconds before the authentication context should no longer be considered valid. This enables the receiving application to determine if the authentication context is still valid. By default, the timeout period is 3600 seconds (1 hour), but the application can set this to a shorter interval.

3. construct a Type1AuthenticationContextManager object and use its buildIdentityContext method to create the IdentityContext object. The application passes the BuildSpec1 object created in the preceding step to the buildIdentityContext method, which returns the IdentityContext object.

The IdentityContext created contains all the authentication context information provided by the application in a format that can be stored and retrieved from the z/OS Identity Cache using classes and methods provided in the `/com/ibm/ictx/identitycontext` package. The receiving application will be able to parse this IdentityContext object to get a Type1AuthenticationContext from which it can retrieve the authentication information. See “Parsing an identity context object for authentication context information” on page 404 for more information.

Once the authenticating application has created an IdentityContext object, it can store it in the z/OS Identity Cache as described in “Storing an identity context object in the z/OS Identity Cache” on page 409. Alternatively, it could forward the IdentityContext to another ICTX application to store into the Identity Cache (as described in “Delegating an identity context object” on page 402).

Delegating an identity context object

When authentication context information is initially generated into an IdentityContext object, a manifest entry is created. When an application passes an identity context reference to another application, that receiving application can later obtain a ManifestInfo object, and from it ascertain the application that created the authentication context, the intended receiving application (if provided by the sending application), and any user ID mapping specified by the sending application.

If the authenticating application forwards the IdentityContext object to another ICTX application, it can delegate the IdentityContext object. Delegating an IdentityContext object creates a new IdentityContext object from the first, with an additional manifest entry indicating the current application, the receiving application, and updated mapping information (if necessary). The receiving application can get an array of ManifestInfo objects from which it can ascertain the application that created the authentication context, as well as the application(s) to which it was delegated.

For example, the authenticating application could create an IdentityContext object with the authentication context information for a particular user, which it delegates to another application to perform an EIM lookup. That application delegates it to a third application, supplying a user ID mapping. The third application stores the IdentityContext object in the z/OS Identity Cache. The receiving application will be able to parse the IdentityContext object for an array of three ManifestInfo objects, from
which it can identify the application that originally created the IdentityContext object, as well as each application to which it was delegated. In this way, a history of the identity context is kept within the identity context itself.

The following figure illustrates the classes and methods an application can use to delegate an identity context object to create a new identity context object with an additional manifest entry.

**Use these objects...**

- ApplicationInfo object representing sending application
- ApplicationInfo object representing receiving application (optional)
- PremappedUserInfo object (optional)

**to construct...**

DelegationSpec1 object

**pass as argument to...**

Type1AuthenticationManager object

delegateIdentityContext method

**which returns...**

IdentityContext object

To delegate an identity context, an application needs to:

1. construct the objects that will be passed as arguments when constructing a DelegationSpec1 object. The objects that will be passed as arguments to the DelegationSpec1 class constructor are:
   a. an ApplicationInfo object that represents the current application. At a minimum, the application provides its identifier name and an instance name that uniquely identifies it in the network. In addition, implementation-specific data can be provided.
   b. optionally, another ApplicationInfo object — this one identifying the application to which the identity context is being delegated. The application might want to provide this information so that the receiving application can verify that it is the intended recipient.
   c. optionally, a PremappedUserInfo object that enables the application to provide a mapping from the local authenticated user ID to a z/OS user ID valid on the system hosting the z/OS Identity Cache. Whether such mappings are required, accepted but not required, or ignored depends on how the z/OS Identity Cache is configured. See “Configuring user ID mapping” on page 394 for more information.

2. construct a DelegationSpec1 object, which represents the information required to delegate an identity context, from the object(s) you created in the preceding step. The application can specify the ApplicationInfo object(s) and the PremappedUserInfo object as arguments to the DelegationSpec1 constructor. If the application is not specifying the intended application recipient for the identity context or is not providing a user ID mapping, a null value can be specified instead of the ApplicationInfo object or the PremappedUserInfo object.

When constructing the DelegationSpec1 object, the application can also specify a timeout value representing the number of seconds before the authentication context should no longer be considered valid. This enables the receiving application to determine if the authentication context is still valid.
default, the timeout period is 3600 seconds (1 hour), but the application can set this to a shorter interval.

3. use the delegateIdentityContext method of the Type1AuthenticationContextManager object to create a new IdentityContext object with an additional manifest entry. The application passes the DelegationSpec1 object created in the preceding step along with the original IdentityContext object to the delegateIdentityContext method, which returns the new IdentityContext object.

**Parsing an identity context object for authentication context information**

An authenticating application specifies authentication context information to create an IdentityContext object which can be stored in the z/OS Identity Cache. The IdentityContext object is a byte array that can be stored and retrieved. Once retrieved from the z/OS Identity Cache, it can be parsed by an application to examine the authentication context information. The following figure illustrates how a receiving application can parse an IdentityContext object to ascertain the authentication context information for a user.

![IdentityContext object diagram]

To parse an identity context object for authentication context information, an application needs to:

1. construct a Type1AuthenticationContextManager object and use its getAuthenticationContext method to parse the identity context byte array. The application passes the IdentityContext object as an argument to the getAuthenticationContext method, which returns a Type1AuthenticationContext object.

2. from the Type1AuthenticationContext object, the application can obtain information about the authenticated user, as well as the authenticating application that built the IdentityContext object and any applications to which the IdentityContext object was delegated.

   To obtain information about the authenticated user, an application:

   a. calls the getAuthenticationInfo method of the Type1AuthenticationContext class. The getAuthenticationInfo method returns an AuthenticationInfo object.

   b. calls methods of the AuthenticationInfo class to obtain the desired information:

<table>
<thead>
<tr>
<th>Table 49: Methods provided by the AuthenticationInfo class</th>
</tr>
</thead>
<tbody>
<tr>
<td>This method</td>
</tr>
<tr>
<td>getUser</td>
</tr>
<tr>
<td>getRegistry</td>
</tr>
<tr>
<td>getMechanism</td>
</tr>
<tr>
<td>getHostName</td>
</tr>
</tbody>
</table>
Table 49: Methods provided by the AuthenticationInfo class (continued)

<table>
<thead>
<tr>
<th>This method</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>getSecurityLabel</td>
<td>the security label associated with this user.</td>
</tr>
<tr>
<td>getImplSpecific</td>
<td>implementation-specific data.</td>
</tr>
</tbody>
</table>

To obtain information about the authenticating application (and any applications to which the IdentityContext was delegated), the application:

a. calls the getManifests method of the Type1AuthenticationContext class. The getManifests method returns an array of ManifestInfo objects—one ManifestInfo object recording the information supplied when the IdentityContext was created, and an additional ManifestInfo object for each time the IdentityContext was delegated. The ManifestInfo objects are in LIFO order.

b. calls methods of the ManifestInfo class as needed to obtain information about the manifest (such as the time it was created, and how much longer it is considered valid) or objects representing the sending application, the receiving application, and any User ID mappings provided by the sending application.

/com/ibm/ictx/identitycontext package

The /com/ibm/ictx/identitycontext package contains interfaces and public classes for storing an identity context in, and retrieving an identity context from, the z/OS Identity Cache. Two storage mechanism classes are provided in this package for interacting with a z/OS Identity Cache. The LdapStorageMechanism class is designed for applications that will access a z/OS Identity Cache remotely using a z/OS IBM TDS server configured with ICTX extended operations, and the zOSStorageMechanism class is for applications that are accessing a z/OS Identity Cache locally. A special factory class (StorageMechanismFactory) for instantiating an object of the appropriate storage-mechanism class based on system configuration settings and/or information supplied by the application is also provided in this package.

The following table lists the interfaces and classes provided in the /com/ibm/ictx/identitycontext package. For complete information on these interfaces and classes, refer to the ICTX Java API reference documentation provided in Javadoc format at z/OS downloads (www.ibm.com/systems/z/os/zos/downloads).

</tr>
</tbody>
</table>
The classes and methods for creating an IdentityContext object from authentication context information, and parsing an IdentityContext object to retrieve the authentication context information, are organized in the \texttt{/com/ibm/ictx/authenticationcontext} package. The IdentityContext class is provided in the \texttt{/com/ibm/ictx/util} package. See “/com/ibm/ictx/authenticationcontext package” on page 400 and “/com/ibm/ictx/util package” on page 409 for more information.

### Creating a storage mechanism object for interacting with the z/OS Identity Cache

A storage mechanism object enables an application to interact with a local or remote z/OS Identity Cache to store and retrieve IdentityContext objects. To access the Identity Cache on a remote z/OS system, an application uses an LdapStorageMechanism object. To access an Identity Cache that is local to an application running on z/OS, an application uses a zOSStorageMechanism object.

In addition to the LdapStorageMechanism and zOSStorageMechanism class constructors, a special factory class (StorageMechanismFactory) is provided for creating the correct type of storage mechanism object based on the location of the executing code, certain configuration settings, and information provided by the application.

- The LdapStorageMechanism class constructor creates a storage mechanism object that enables an application running on a z/OS or non-z/OS system to interact with an Identity Cache on a remote z/OS system. In order to connect to the remote system, a z/OS IBM TDS server with ICTX extended operations will need to be identified, and bind credentials will need to be supplied.

  An application running on a non-z/OS system must provide this information in a hash table supplied to the LdapStorageMechanism class constructor. The hash table should include values specifying:
  - a URL for the z/OS IBM TDS server that provides remote access to the Identity Cache, such as \texttt{ldap://some.big.host}
  - a bind DN
  - a bind password

  For example:

  ```java
  Hashtable bindInfo = new Hashtable();
  bindInfo.put(Context.PROVIDER_URL, "ldap://myserver.com");
  bindInfo.put(Context.SECURITY_PRINCIPAL, "racfid=user01,cn=ICTX");
  bindInfo.put(Context.SECURITY_CREDENTIALS, "password");
  ```

  An application running on a z/OS system can also provide this information in a hash table supplied to the LdapStorageMechanism class constructor, or it could instead supply this information as default values in an in-storage copy of the \texttt{IRR.ICTX.DEFAULTS} profile in the LDAPBIND class. See “Configuring the z/OS Identity Cache” on page 394 for more information.

- The zOSStorageMechanism class constructor creates a storage mechanism object that provides direct access to the z/OS Identity Cache for applications running locally.

- The getStorageMechanism method of the StorageMechanismFactory class returns either the zOSStorageMechanism or LdapStorageMechanism based on:
  - whether the application is running on a z/OS or non-z/OS system.
– an input hash table object passed as an argument to the getStorageMechanism method specifying a URL for a z/OS IBM TDS server, a bind DN, and a bind password.
– for z/OS applications, default connection information specified in an in-storage copy of the IRR.ICTX.DEFAUTLS profile in the LDAPBIND class.

To determine which storage mechanism to run, the factory class uses the following criteria:

• If the Java application is not running on z/OS:
  – If no URL for a z/OS IBM TDS server was provided by the application, an error exception is returned.
  – If a URL is provided by the application, the application can access the remote Identity Cache, and an instance of the LdapStorageMechanism is returned.

• If the Java application is running on z/OS:
  – If no URL is provided and the in-storage copy of the IRR.ICTX.DEFAULTS profile has no URL, then access to the local Identity Cache is assumed, and an instance of the zOSStorageMechanism class is returned.
  – If a URL is provided, or the in-storage copy of the IRR.ICTX.DEFAULTS profile has a URL, that matches the value in the in-storage copy of the APPLDATA field, then access to the local Identity Cache is configured and an instance of the zOSStorageMechanism class is returned.
  – Otherwise, if the URL value from the hash table, or the in-storage copy of the IRR.ICTX.DEFAULTS profile, doesn't match the value in the in-storage copy of the APPLDATA field, access is required to a remote Identity Cache and an instance of the LdapStorageMechanism class is returned.

The following table shows the possible scenarios for accessing the Identity Cache. Note that the StorageMechanismFactory returns a zOSStorageMechanism object when the Identity Cache is local, and an LDAPStorageMechanism object when remote.

</table>
Storing an identity context object in the z/OS Identity Cache

To store an IdentityContext object in the z/OS Identity Cache, the application uses the storeIdentityContext method of the storage mechanism object that is providing access to the Identity Cache — either an LdapStorageMechanism or zOSStorageMechanism object. The application specifies the IdentityContext object as an argument to the storeIdentityContext method.

The storeIdentityContext method returns an IdentityContextCredential object for the stored identity context. An IdentityContextCredential object represents a credential that enables an application to retrieve an IdentityContext object from the z/OS Identity Cache. An IdentityContextCredential object consists of a user name and a reference. The user name is a flag that indicates the data is stored in an Identity Cache, and the reference is what is needed to retrieve the data from the Identity Cache. The user name and reference can be returned by the getUserName and getReference methods, and then forwarded to the application that needs to retrieve the IdentityContext object.

Retrieving an identity context object from the z/OS Identity Cache

To retrieve an IdentityContext object from the z/OS Identity Cache, an application uses the retrieveIdentityContext method of the storage mechanism object that is providing access to the Identity Cache — either an LdapStorageMechanism or zOSStorageMechanism object. The application specifies an IdentityContextCredential object representing the stored identity context as an argument to the retrieveIdentityContext method, which returns the IdentityContext object.

An IdentityContextCredential object consists of a user name and a reference that will have been forwarded from the application that stored the IdentityCache object to the application that needs to retrieve it. Using the user name and reference strings, the application constructs the IdentityContextCredential object, and passes it to the retrieveIdentityContext method to obtain the IdentityContext.

/com/ibm/ictx/util package

The /com/ibm/ictx/util package contains utility classes used by the classes in the other two packages. Classes are provided for representing an identity context and exceptions thrown by other classes.

<table>
<thead>

</tr>
</tbody>
</table>

Sample ICTX application

The following sample code illustrates the steps an application might perform to store an identity context in, and later retrieve it from, the z/OS Identity Cache. The code for both the authenticating application (which constructs the IdentityContext object and stores it in the Identity Cache), and the server application (which retrieves the IdentityContext object and parses it for the user information) is shown.

This first example shows the code for the authenticating application. It builds the IdentityContext object, creates a storage mechanism object for interacting with the z/OS Identity Cache, and stores the IdentityContext object into the Identity Cache. It then passes the user name and a reference for the IdentityContextCredential to the server application so that it can retrieve the IdentityContext object.

    StorageMechanismFactory smf = new StorageMechanismFactory();
  }
}
StorageMechanism sm = smf.getStorageMechanism(iCacheLocation);
IdentityContextCredential userHandle = sm.storeIdentityContext(iContext, timeoutValue);

return userHandle;
} // storeUserInCache

/**
 * Method: main
 * This method stores information about an authenticated
 * user in the z/OS Identity Cache and passes the Identity
 * Cache credentials to a service that only accepts a
 * user id and password.
 */
public void main() {

String userName = "cn=Joe User,c=us";
String userRegistry = "Some Ldap User Registry";
String registryType = "LDAP";
String location = "ldap://Some.AIX.Directory";

try {
    // Step 1: Authenticate the user
    // Step 2: Store the authenticated user's info in the Identity Cache
    IdentityContextCredential userh = storeUserInCache(userName, userRegistry,registryType,location);
    // Step 3: Pass the identity context userid and reference
    // to the service that normally accepts a userID and password
    RetrieveSample rs = new RetrieveSample();
    rs.sampleService(userh.getUserName(), userh.getReference());
} catch (Exception e) {
    System.out.println("Exception Occurred: " + e);
}
} // main

This next example shows the code for the server application. It constructs an IdentityContextCredential object using the user name and reference string passed by the authenticating application. It then creates a storage mechanism object for interacting with the z/OS Identity Cache, and retrieves the IdentityContext object. It then parses this object to get the user authentication information.

    // Step 3. perform the service
    // sampleService
Chapter 15. Accessing RACF remotely to perform authorization checks and create audit records

Note: An enhanced version of this support is now shipped with IBM Tivoli Directory Server for z/OS. If you want to use the enhanced support, you must modify your plugin statement for the ICTX plug-in in your server configuration file. See z/OS IBM Tivoli Directory Server Plug-in Reference for z/OS for more information about configuring the enhanced ICTX plug-in.

Remote authorization and auditing allows resource managers that do not reside on z/OS to centralize authorization decisions and security event logging using z/OS Security Server RACF through the IBM TDS server. These services are provided through LDAP extended operations. The requests come in the form of a DER-encoding of the ASN.1 syntax. The following sections provide details on these remote authorization and auditing requests.

Because there are many mechanisms available for user authentication and mapping, the remote services do not provide an authentication option. Applications that use the authorization service are responsible for authenticating users. Applications that expect users to provide a RACF user ID and password can authenticate by performing a simple bind to the SDBM component of the IBM Tivoli Directory Server. For details on how to bind to SDBM refer to z/OS IBM Tivoli Directory Server Administration and Use for z/OS. If mapping from a non-RACF user ID to a RACF user ID is to be performed during authentication, another option is to use the native authentication feature of the LDBM component of the IBM TDS LDAP server. Configuration and use of the IBM TDS native authentication feature is also documented in z/OS IBM Tivoli Directory Server Administration and Use for z/OS.

Note that this information describes remote authorization and audit specifically. For full details on auditing controls in z/OS, see z/OS Security Server RACF Auditor's Guide.

Using remote authorization and audit

The remote authorization and audit services are enabled when the ICTX extended operations component is configured for IBM Tivoli Directory Server. Refer to “Configuring the IBM Tivoli Directory Server for remote services support” on page 399 for instructions.

An application or resource manager that uses the remote audit or authorization LDAP extended operation must be capable of generating a request, sending it through the network to the appropriate z/OS IBM TDS server, and interpreting the response from the z/OS IBM TDS server. The following steps represent the typical sequence of events that are specific to the LDAP extended operations for the remote authorization and auditing:

1. The application must perform a simple bind to the server using an authorized racfid=userid, cn=ictx bind distinguished name.
2. The application must build a DER-encoded extended operation request having the defined ASN.1 syntax that is specific to the audit or authorization request. That request can then be included with the z/OS IBM TDS server handle and specific request OID on the LDAP client call, such as ldap_extended_operation_s(), to build the LDAP message and send it to the server.
3. The z/OS IBM TDS receives the request and routes it to the ICTX component, where it is decoded and processed. ICTX verifies the correct syntax and the requestor's authority before invoking the SAF authorization check or audit service to satisfy the request. The result of the SAF service is a DER-encoded response that LDAP returns.
4. The application must decode the response in order to interpret the results. A nonzero LdapResult code indicates the request was not processed by the ICTX component. A nonzero LdapResult is accompanied by a reason string in the response that may provide additional diagnostic information.

Note: A zero LdapResult code does not necessarily imply the request was processed successfully (or for authorization, that a user has the specified access). It does, however, indicate that an extended
operation ResponseValue was returned. The application should verify that the ICTX ResponseCode within the ResponseValue indicates success (0). A nonzero ResponseCode indicates one or more request items resulted in errors (or unauthorized users). The application should check the MajorCode within each response item to determine which returned failures. The application should be aware that ICTX may not return a response item corresponding to each request item in the event of a severe error, such as an error encountered in the DER encoding.

The application may send as many requests as needed throughout a single bound session, and should unbind from IBM TDS when it has finished processing ICTX requests.

Profile authorizations for working with remote services

In order to recognize that a client is authorized to use remote services, the remote service requestor or client is required to have specific RACF authorization. User distinguished names with the suffix \texttt{cn=ictx} bind through the z/OS IBM TDS ICTX component. These names have the following format:

\texttt{racfid=userid,cn=ictx}

The password for the distinguished name must be the RACF user ID's password and this password is validated by RACF. Bind distinguished names are authenticated using native authentication. Only simple bind is supported. Kerberos and SSL binds are not supported.

If the RACF user ID begins with a pound sign (#), it must be preceded by a backslash (\) escape character. Pound sign characters in other positions of the user ID do not need to be escaped. For example:

\texttt{racfid=\#userid\#id,cn=ictx}

Once accepted as a valid request, the bind user's authorization to use the services is verified. For remote authorization, the user must have at least READ access to FACILITY class profile \texttt{IRR.LDAP.REMOTE.AUTH} in order to check the user's own access to a resource. To check another user's access, the user must have at least UPDATE access to FACILITY class profile \texttt{IRR.LDAP.REMOTE.AUTH}. For example:

\begin{verbatim}
RDEFINE FACILITY IRR.LDAP.REMOTE.AUTH UACC(NONE)
PERMIT IRR.LDAP.REMOTE.AUTH CLASS(FACILITY) ID(BINDUSER) ACCESS(UPDATE)
\end{verbatim}

For remote auditing requests, the bind user must have at least READ access to FACILITY class profile \texttt{IRR.LDAP.REMOTE.AUDIT}.

\begin{verbatim}
RDEFINE FACILITY IRR.LDAP.REMOTE.AUDIT UACC(NONE)
PERMIT IRR.LDAP.REMOTE.AUDIT CLASS(FACILITY) ID(BINDUSER) ACCESS(READ)
\end{verbatim}

Authority to use the remote services is determined when the user binds through ICTX.

The remote audit operation calls the SAF service \texttt{R_auditx}. The service runs under the identity of the IBM TDS server, which must have the appropriate service authorization. The user ID associated with the IBM TDS server must be granted at least READ access to FACILITY class profile \texttt{IRR.RAUDITX}.

\begin{verbatim}
RDEFINE FACILITY IRR.RAUDITX UACC(NONE)
PERMIT IRR.RAUDITX CLASSS(FACILITY) ID(LDAPSRV) ACCESS(READ)
\end{verbatim}

Remote authorization requests

Remote authorization requests sent to ITDS are processed and result in calls to the RACROUTE REQUEST=AUTH SAF service. The results of the RACROUTE REQUEST=AUTH service are returned to the caller. Additional information about RACROUTE REQUEST=AUTH can be found in \textit{z/OS Security Server RACROUTE Macro Reference}.  

414 z/OS: Integrated Security Services Enterprise Identity Mapping (EIM) Guide and Reference
The remote authorization request must contain the DER-encoding of the ASN.1 syntax. The following is the remote authorization request syntax:

```
Request OID:  1.3.18.0.2.12.66
RequestValue ::= SEQUENCE  {
  RequestVersion INTEGER,
  ItemList  SEQUENCE of
    Item    SEQUENCE {
      ItemVersion INTEGER,
      ItemTag INTEGER,
      UserOrGroup IA5String,
      Resource IA5String,
      Class    IA5String,
      Access   INTEGER,
      LogString IA5String
    }
}
```

Where:

**RequestValue**
The name for the entire sequence of authorization request data.

**RequestVersion**
The format of the request value. Version 1 indicates a user authorization request; each individual Item in the ItemList will be an authorization request for a RACF userid. Version 2 indicates a user authorization or a group authorization request; each individual Item in the ItemList will be an authorization request for either a RACF userid or a RACF group.

**ItemList**
A sequence of one or more items, which allows for multiple authorization checks within a single ICTX request. The size of the entire encoded RequestValue should be limited to 16 million bytes unless your encoding routine or LDAP client imposes a stricter limit. If RequestVersion is 2, the ItemList can be a mixture of user authorization and group authorization items.

**Item**
A sequence of data that represents a single authorization check.

**ItemVersion**
The format of the individual item. Version 1 indicates an authorization request for a RACF userid. Version 2 indicates an authorization request for a RACF group.

**ItemTag**
An integer set by the client for each request item and echoed in each response item. Its purpose is to assist the client in correlating multiple request responses, and has no influence on the authorization logic or logging.

**UserOrGroup**
If ItemVersion is 1, a RACF userid whose authority is being checked. Its length cannot exceed 8 characters. If the length is zero, the user value defaults to the user ID associated with the bind user.  
If ItemVersion is 2, a RACF group ID whose authority is being checked. Its length must be from 1 and 8 characters. Optimizations used when performing a userid authorization check are not available when performing a group ID authorization check. For this reason, it is likely that group authorization checks will execute more slowly than userid authorization checks.

Be aware that this field must be specified in uppercase, because RACF user and group names are uppercase, and the remote authorization service will not convert lowercase characters to uppercase.

**Resource**
A name to be matched against a RACF profile for authorization checking. The string may not include blank characters. Its length may be from 1 to the maximum RACF profile length defined for the specified class.
**Class**
A defined RACF general resource class. It cannot be DATASET, USER, or GROUP. Its length may be from 1 to 8 characters.

If you are checking authorization to resources protected by profiles in a grouping/member class, specify the member class name in the remote authorization request. In order to obtain accurate results in this case, ensure that the administrator has issued SETROPTS RACLST for the member class.

**Access**
The level of authority requested. It must be one of the following integer values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'01'</td>
<td>READ</td>
</tr>
<tr>
<td>X'02'</td>
<td>UPDATE</td>
</tr>
<tr>
<td>X'03'</td>
<td>CONTROL</td>
</tr>
<tr>
<td>X'04'</td>
<td>ALTER</td>
</tr>
</tbody>
</table>

**LogString**
Any character data from 0 to 200 characters in length. It is appended to an ICTX-defined string in the SMF log record.

The following is the ASN.1 syntax for the remote authorization response message:

```asn1
Response OID: 1.3.18.0.2.12.67
ResponseValue ::= SEQUENCE {
    ResponseVersion INTEGER,
    ResponseCode  INTEGER,
   ItemList   SEQUENCE of
        Item  SEQUENCE{
            ItemVersion INTEGER,
            ItemTag INTEGER,
            MajorCode   INTEGER,
            MinorCode1  INTEGER,
            MinorCode2  INTEGER,
            MinorCode3  INTEGER
        }
}
```

Where:

**ResponseValue**
The name for the entire sequence of authorization response data.

**ResponseVersion**
The format of the response value. Version 1 is the only supported format.

**ResponseCode**
The greatest error encountered while processing the request. See Table 54 on page 417 for more details on supported ResponseCodes.

**ItemList**
A sequence of one or more items, which allows for multiple authorization results within a single ICTX response.

**Item**
A sequence of data that represents the results from a single authorization check.

**ItemVersion**
The format of the individual item. Version 1 is the only supported format.

**ItemTag**
An integer echoed from the corresponding request ItemTag. The purpose of the ItemTag is to assist the client in correlating multiple request responses. ItemTag has no influence on the authorization logic or logging.

**MajorCode**
An integer value representing the result of the authorization check. See Table 55 on page 417 for more details on error major codes.
Remote authorization ResponseCodes

Use the following table to understand the response codes generated from the remote authorization processing. The ResponseCode represents the greatest error encountered. You may experience situations in which a request item generates an error that is not reflected in the ResponseCode, because that value is overridden by a higher-severity error.

<table>
<thead>
<tr>
<th>ResponseCode (decimal)</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>All request items were processed successfully</td>
</tr>
<tr>
<td>28</td>
<td>Empty item list. No items are found within the ItemList sequence of the extended operation request, so no response items are returned.</td>
</tr>
<tr>
<td>61-70</td>
<td>The specified RequestVersion is not supported. Subtract 60 from the value to determine the highest RequestVersion that the server supports. ResponseCode 61 indicates the server supports version 1 requests only. ResponseCode 62 indicates the highest supported request level is 2.</td>
</tr>
<tr>
<td>other</td>
<td>Errors or warnings encountered while processing one or more request items. The value represents the highest MajorCode in the set of all response items. Verify the major and minor codes returned for each item.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>MajorCode (decimal)</th>
<th>Meaning</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Authorized</td>
<td>The user has the requested access to the resource.</td>
</tr>
<tr>
<td>2</td>
<td>Warning mode</td>
<td>The user has the requested access because warning mode is enabled for the resource. Warning mode is a feature of RACF that allows installations to try out security policies. Installations can define a profile with the WARNING attribute. When RACF performs an authorization check using the profile, it will log the event (if there are audit settings) and allow the authorization check to pass successfully. The log records can be monitored to ensure the new policy is operating as expected before putting the policy into production by turning off the WARNING attribute.</td>
</tr>
<tr>
<td>4</td>
<td>Undetermined</td>
<td>No decision could be made. The specified resource is not protected by RACF, or RACF is not installed.</td>
</tr>
</tbody>
</table>
### Table 55: Remote authorization MajorCodes (continued)

<table>
<thead>
<tr>
<th>MajorCode (decimal)</th>
<th>Meaning</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>Unauthorized</td>
<td>The user does not have the requested access to the resource.</td>
</tr>
<tr>
<td>12</td>
<td>RACROUTE error</td>
<td>The RACROUTE REQUEST=AUTH service returned an unexpected error. Compare the returned minor codes with the SAF &amp; RACF codes documented in Security Server RACROUTE Macro Reference.</td>
</tr>
<tr>
<td>14</td>
<td>initACEE error</td>
<td>The initACEE callable service returned an unexpected error. Compare the returned minor codes with the SAF &amp; RACF codes documented in Security Server RACF Callable Services.</td>
</tr>
<tr>
<td>16</td>
<td>Request value error</td>
<td>A value specified in the extended operation request is incorrect or unsupported. Check the returned minor codes to narrow the reason.</td>
</tr>
<tr>
<td>20</td>
<td>Request encoding error</td>
<td>A decoding error was encountered indicating the extended operation request contains non-compliant DER encoding, or does not match the documented ASN.1 syntax.</td>
</tr>
<tr>
<td>24</td>
<td>Insufficient authority</td>
<td>The requestor does not have sufficient authority for the requested function. The userid associated with the LDAP bind user must have the appropriate access to the FACILITY class profile IRR.LDAP.REMOTE.AUTH.</td>
</tr>
<tr>
<td>100</td>
<td>Internal error</td>
<td>An internal error was encountered within the ICTX component.</td>
</tr>
</tbody>
</table>

### Remote authorization audit controls

The auditor can specify whether to log access attempts based on user, class, resource, or any criteria as described in *z/OS Security Server RACF Auditor's Guide*. The SMF type 80 records generated can be unloaded by using the IRRADU00 utility.

### Remote auditing requests

Remote audit requests sent to ITDS are processed and result in calls to the r_auditx (IRRSAX00) SAF callable service. The results of the r_auditx service are returned to the caller. Additional information about the r_auditx service can be found in *z/OS Security Server RACF Callable Services*.

As with remote authorization, remote auditing also uses the DER-encoded ASN.1 syntax. The remote audit request is displayed as the following:

Request OID: 1.3.18.0.2.12.68

```
RequestValue ::= SEQUENCE {
  RequestVersion INTEGER,
  ItemList SEQUENCE of
    Item SEQUENCE {
      ItemVersion INTEGER,
      ItemTag INTEGER
      LinkValue OCTET STRING SIZE(8),
      Violation BOOLEAN,
      Event INTEGER,
      Qualifier INTEGER,
      Class IA5String,
      Resource IA5String,
      Logstring IA5String,
      DataFieldList SEQUENCE of
        DataField SEQUENCE{
          Type INTEGER,
          Value IA5String
        }}
}
Where:

**RequestValue**
The name for the entire sequence of the audit request data.

**RequestVersion**
The format of the request value. Version 1 is the only currently supported format.

**ItemList**
A sequence of one or more items, allowing multiple audit records to be written with a single ICTX request. IBM recommends limiting the size of the entire encoded RequestValue to 16 million bytes; however, your encoding routine or LDAP client may impose a stricter limit.

**Item**
A sequence of data that represents a single audit record.

**ItemVersion**
The format of the individual item. Version 1 is the only currently supported format.

**ItemTag**
An integer set by the client for each request item and echoed in each response item. Its purpose is to assist the client in correlating multiple request responses. The ItemTag value does not influence the audit processing, and does not appear in the audit record.

**LinkValue**
8 bytes of data used to mark related audit records. Specify 8 bytes of zero (X'00') if no such marking is needed.

**Violation**
A boolean value that indicates whether the event represents a violation (nonzero ~ TRUE) or not (zero ~ FALSE). The value is used in the R_auditx logging decision.

**Event**
An integer 1 to 7 that identifies the security event type. The possible values are:

1. Authentication
2. Authorization
3. Authorization Mapping
4. Key Management
5. Policy Management
6. Administrator Configuration
7. Administrator Action

**Qualifier**
An integer 0 to 3 that describes the event result. The possible values are:

0. Success
1. Information
2. Warning
3. Failure
**Class**
A defined RACF general resource class that may be used for audit logging determination. It cannot be DATASET, USER, or GROUP. Its length may be from 0 to 8 characters.

**Resource**
A name that may be matched against a RACF profile in the specified class for audit logging determination. Its length may be from 0 to 246 characters.

**LogString**
Any character data from 0 to 200 characters in length. It is appended to an ICTX-defined string in the SMF log record.

**DataFieldList**
A sequence of type/value pairs that will be logged as SMF relocates. Any number of relocates may be included, but the R_auditx service limits the total amount of this relocate data to 20 kilobytes per record.

**DataField**
A sequence of data that represents a single relocate section in an audit record.

**Type**
An integer 100 to 116 corresponding to a defined relocate number. The possible values are:

- 100 SAF identifier for bind user
- 101 Requestor’s bind user identifier
- 102 Originating security domain
- 103 Originating registry / realm
- 104 Originating user name
- 105 Mapped security domain
- 106 Mapped registry / realm
- 107 Mapped user name
- 108 Operation performed
- 109 Mechanism / object name
- 110 Method / function used
- 111 Key / certificate name
- 112 Caller subject initiating security event
- 113 Date and time security event occurred
- 114 Application specific data
- 115 Identifier for the client submitting the remote audit request

Accessing RACF remotely to perform authorization checks and create audit records 421
Version of the client submitting the remote audit request

Value

Character data of the associated type that is included in the audit record.

The remote audit response is displayed as the following:

```
Response OID: 1.3.18.0.2.12.69
ResponseValue ::= SEQUENCE {
  ResponseVersion INTEGER,
  ResponseCode INTEGER,
  ItemList SEQUENCE of
    Item SEQUENCE{
      ItemVersion INTEGER,
      ItemTag INTEGER,
      MajorCode INTEGER,
      MinorCode1 INTEGER,
      MinorCode2 INTEGER,
      MinorCode3 INTEGER
    }
}
```

Where:

**ResponseValue**

The name for the entire sequence of audit response data.

**ResponseVersion**

The format of the response value. Version 1 is the only supported format.

**ResponseCode**

The greatest error encountered while processing the request. See Table 57 on page 423 for more details on supported ResponseCodes.

**ItemList**

A sequence of one or more items, which allows for multiple audit results within a single ICTX response.

**Item**

A sequence of data that represents a single audit request.

**ItemVersion**

The format of the individual item. Version 1 is the only supported format.

**ItemTag**

An integer echoed from the corresponding request ItemTag. The purpose of the ItemTag is to assist the client in correlating multiple request responses. The ItemTag does not influence the audit processing, and does not appear in the audit record.

**MajorCode**

An integer value representing the result of the audit request. See Table 58 on page 423 for more details on error major codes.

**MinorCode1**

Additional details about the error. See Table 59 on page 424 for more details on error minor codes.

**Minor Code2**

Additional details about the error.

**Minor Code3**

Additional details about the error.

**Remote auditing response codes**

Use the following table to understand the response codes generated from the remote auditing processing. The ResponseCode represents the greatest error encountered. You may experience situations in which a request item generates an error that is not reflected in the ResponseCode, because that value is overridden by a higher-severity error.
### Table 57: Remote auditing ResponseCodes

<table>
<thead>
<tr>

<tbody>
<tr>
<td>0</td>
<td>Success</td>
<td>The event is logged successfully.</td>
</tr>
<tr>
<td>2</td>
<td>Warning mode</td>
<td>The event is is logged, and warning mode is set for the specified resource. Warning mode is a feature of RACF that allows installations to try out security policies. Installations can define a profile with the WARNING attribute. When RACF performs an authorization check using the profile, it will log the event (if there are audit settings) and allow the authorization check to pass successfully. The log records can be monitored to ensure the new policy is operating as expected before putting the policy into production by turning off the WARNING attribute. A remote client resource manager using the remote audit service may simulate RACF warning mode logic after submitting an audit request for a failing authorization event. If the MajorCode in the response item indicates the matching resource profile has the warning mode set, the remote client resource manager may allow the check to pass successfully.</td>

Remote audit controls

The remote audit service uses the R_auditx callable service documented in z/OS Security Server RACF Callable Services to generate SMF type 83 (subtype 4) audit records. The IRRADU00 utility can then be used to unload the generated SMF type 83 subtype 4 records. Whether or not the R_auditx service actually writes an audit record for an event, however, depends on the RACF audit controls. If the audit controls do not direct RACF to log an event that was specified in a remote audit request, the R_auditx service will not generate an audit record. If the remote application sends a remote audit request for an operation that has not been configured to be logged, this will be reflected in the remote audit response (a MajorCode of 3 indicates that the event was not logged because it is not required).

There are several ways the RACF auditor can enable logging of events from remote audit requests. For example, because the remote application will have used a RACF user ID to authenticate with z/OS through an LDAP bind operation, the auditor can enable logging for all remote audit events by setting UAUDIT for that RACF user ID.

If the remote application has specified a Class and Resource in the remote auditing requests, the auditor can enable logging for the class (using the SETROPTS LOGOPTIONS command) or the resource (using the ADDSD AUDIT, ALTDSD AUDIT, or ALTDSD GLOBALAUDIT commands). To do this, the auditor must know the class and resource specified by the application submitting the remote audit requests.

An effective way to gain granular control over which remote application events are logged, is to use the RACF dynamic class descriptor table (dynamic CDT) to define custom classes to represent specific remote applications. Once you have defined a custom class to represent a remote application, you can create

### Table 59: Remote auditing MinorCodes. Remote auditing MinorCodes (continued)

</tr>
</tbody>
</table>
resource profiles in the class to represent specific user operations that the application supports. Then, by manipulating the auditing options for the class and profiles, the RACF auditor can determine the type of information logged. For example, imagine a travel application that runs remotely and supports user operations to:

- book a flight
- cancel a flight booking
- check seat availability
- view flight information

A new custom class, @FLIGHTS is created in the dynamic CDT to represent this remote application, and profiles BOOK, CANCEL, SEATCHECK, and VIEW are created in this new class to represent the user operations that are supported. A remote audit request Item will be sent by the remote application for each user operation, and the Class and Resource parameters for each Item will identify the travel application and the particular operation. The Class and Resource parameters are used on the remote audit requests for logging determination on the z/OS server. So even though the remote audit record will be sent for each operation, whether these events are actually logged will depend on how auditing is configured for the @FLIGHTS class and the BOOK, CANCEL, SEATCHECK, and VIEW profiles. This gives the RACF auditor granular control over which user operations are logged.

Configuration of the audit settings on the profiles enables the RACF auditor to, for example, log all BOOK and CANCEL requests while ignoring VIEW and SEATCHECK requests.

**SMF Record Type 83 subtype 4 records**

The remote audit service logs events as SMF Type 83 subtype 4 records that can be unloaded using the IRRADU00 utility. Each logged event has a unique event code with a corresponding event code qualifier, or value that indicates if the event succeeded, resulted in warning or failure, or was simply logging event information. The event codes are described in the following table:

<table>
<thead>
<tr>
<th>Event</th>
<th>Command / Service</th>
</tr>
</thead>
<tbody>

Appendix A. Accessibility

Accessible publications for this product are offered through IBM Knowledge Center (www.ibm.com/support/knowledgecenter/SSLTBW/welcome).

If you experience difficulty with the accessibility of any z/OS information, send a detailed email message to mhvrcfs@us.ibm.com.

Accessibility features

Accessibility features help users who have physical disabilities such as restricted mobility or limited vision use software products successfully. The accessibility features in z/OS can help users do the following tasks:

• Run assistive technology such as screen readers and screen magnifier software.
• Operate specific or equivalent features by using the keyboard.
• Customize display attributes such as color, contrast, and font size.

Consult assistive technologies

Assistive technology products such as screen readers function with the user interfaces found in z/OS. Consult the product information for the specific assistive technology product that is used to access z/OS interfaces.

Keyboard navigation of the user interface

You can access z/OS user interfaces with TSO/E or ISPF. The following information describes how to use TSO/E and ISPF, including the use of keyboard shortcuts and function keys (PF keys). Each guide includes the default settings for the PF keys.

• z/OS TSO/E Primer
• z/OS TSO/E User's Guide
• z/OS ISPF User's Guide Vol I

Dotted decimal syntax diagrams

Syntax diagrams are provided in dotted decimal format for users who access IBM Knowledge Center with a screen reader. In dotted decimal format, each syntax element is written on a separate line. If two or more syntax elements are always present together (or always absent together), they can appear on the same line because they are considered a single compound syntax element.

Each line starts with a dotted decimal number; for example, 3 or 3.1 or 3.1.1. To hear these numbers correctly, make sure that the screen reader is set to read out punctuation. All the syntax elements that have the same dotted decimal number (for example, all the syntax elements that have the number 3.1) are mutually exclusive alternatives. If you hear the lines 3.1 USERID and 3.1 SYSTEMID, your syntax can include either USERID or SYSTEMID, but not both.

The dotted decimal numbering level denotes the level of nesting. For example, if a syntax element with dotted decimal number 3 is followed by a series of syntax elements with dotted decimal number 3.1, all the syntax elements numbered 3.1 are subordinate to the syntax element numbered 3.
Certain words and symbols are used next to the dotted decimal numbers to add information about the syntax elements. Occasionally, these words and symbols might occur at the beginning of the element itself. For ease of identification, if the word or symbol is a part of the syntax element, it is preceded by the backslash (\) character. The * symbol is placed next to a dotted decimal number to indicate that the syntax element repeats. For example, syntax element *FILE with dotted decimal number 3 is given the format 3 \* FILE. Format 3* FILE indicates that syntax element FILE repeats. Format 3* \* FILE indicates that syntax element * FILE repeats.

Characters such as commas, which are used to separate a string of syntax elements, are shown in the syntax just before the items they separate. These characters can appear on the same line as each item, or on a separate line with the same dotted decimal number as the relevant items. The line can also show another symbol to provide information about the syntax elements. For example, the lines 5.1*, 5.1 LASTRUN, and 5.1 DELETE mean that if you use more than one of the LASTRUN and DELETE syntax elements, the elements must be separated by a comma. If no separator is given, assume that you use a blank to separate each syntax element.

If a syntax element is preceded by the % symbol, it indicates a reference that is defined elsewhere. The string that follows the % symbol is the name of a syntax fragment rather than a literal. For example, the line 2.1 %OP1 means that you must refer to separate syntax fragment OP1.

The following symbols are used next to the dotted decimal numbers.

? indicates an optional syntax element
The question mark (?) symbol indicates an optional syntax element. A dotted decimal number followed by the question mark symbol (?) indicates that all the syntax elements with a corresponding dotted decimal number, and any subordinate syntax elements, are optional. If there is only one syntax element with a dotted decimal number, the ? symbol is displayed on the same line as the syntax element, (for example 5? NOTIFY). If there is more than one syntax element with a dotted decimal number, the ? symbol is displayed on a line by itself, followed by the syntax elements that are optional. For example, if you hear the lines 5 ?, 5 NOTIFY, and 5 UPDATE, you know that the syntax elements NOTIFY and UPDATE are optional. That is, you can choose one or none of them. The ? symbol is equivalent to a bypass line in a railroad diagram.

! indicates a default syntax element
The exclamation mark (!) symbol indicates a default syntax element. A dotted decimal number followed by the ! symbol and a syntax element indicate that the syntax element is the default option for all syntax elements that share the same dotted decimal number. Only one of the syntax elements that share the dotted decimal number can specify the ! symbol. For example, if you hear the lines 2? FILE, 2.1! (KEEP), and 2.1 (DELETE), you know that (KEEP) is the default option for the FILE keyword. In the example, if you include the FILE keyword, but do not specify an option, the default option KEEP is applied. A default option also applies to the next higher dotted decimal number. In this example, if the FILE keyword is omitted, the default FILE (KEEP) is used. However, if you hear the lines 2? FILE, 2.1, 2.1.1! (KEEP), and 2.1.1 (DELETE), the default option KEEP applies only to the next higher dotted decimal number, 2.1 (which does not have an associated keyword), and does not apply to 2? FILE. Nothing is used if the keyword FILE is omitted.

* indicates an optional syntax element that is repeatable
The asterisk or glyph (*) symbol indicates a syntax element that can be repeated zero or more times. A dotted decimal number followed by the * symbol indicates that this syntax element can be used zero or more times; that is, it is optional and can be repeated. For example, if you hear the line 5.1* data area, you know that you can include one data area, more than one data area, or no data area. If you hear the lines 3* , 3 HOST, 3 STATE, you know that you can include HOST, STATE, both together, or nothing.

Notes:
1. If a dotted decimal number has an asterisk (*) next to it and there is only one item with that dotted decimal number, you can repeat that same item more than once.
2. If a dotted decimal number has an asterisk next to it and several items have that dotted decimal number, you can use more than one item from the list, but you cannot use the items more than once each. In the previous example, you can write HOST STATE, but you cannot write HOST HOST.
3. The * symbol is equivalent to a loopback line in a railroad syntax diagram.

* indicates a syntax element that must be included

The plus (+) symbol indicates a syntax element that must be included at least once. A dotted decimal number followed by the + symbol indicates that the syntax element must be included one or more times. That is, it must be included at least once and can be repeated. For example, if you hear the line 6.1+ data area, you must include at least one data area. If you hear the lines 2+, 2 HOST, and 2 STATE, you know that you must include HOST, STATE, or both. Similar to the * symbol, the + symbol can repeat a particular item if it is the only item with that dotted decimal number. The + symbol, like the * symbol, is equivalent to a loopback line in a railroad syntax diagram.
Notices

This information was developed for products and services that are offered in the USA or elsewhere.

IBM may not offer the products, services, or features discussed in this document in other countries. **IBM Online Privacy Statement**

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user, or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering’s use of cookies is set forth below.

Depending upon the configurations deployed, this Software Offering may use session cookies that collect each user’s name, email address, phone number, or other personally identifiable information for purposes of enhanced user usability and single sign-on configuration. These cookies can be disabled, but disabling them will also eliminate the functionality they enable.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see IBM’s Privacy Policy at ibm.com/privacy and IBM’s Online Privacy Statement at ibm.com/privacy/details in the section entitled “Cookies, Web Beacons and Other Technologies,” and the “IBM Software Products and Software-as-a-Service Privacy Statement” at ibm.com/software/info/product-privacy.

---

**Policy for unsupported hardware**

Various z/OS elements, such as DFSMS, JES2, JES3, and MVS™, contain code that supports specific hardware servers or devices. In some cases, this device-related element support remains in the product even after the hardware devices pass their announced End of Service date. z/OS may continue to service element code; however, it will not provide service related to unsupported hardware devices. Software problems related to these devices will not be accepted for service, and current service activity will cease if a problem is determined to be associated with out-of-support devices. In such cases, fixes will not be issued.
Minimum supported hardware

The minimum supported hardware for z/OS releases identified in z/OS announcements can subsequently change when service for particular servers or devices is withdrawn. Likewise, the levels of other software products supported on a particular release of z/OS are subject to the service support lifecycle of those products. Therefore, z/OS and its product publications (for example, panels, samples, messages, and product documentation) can include references to hardware and software that is no longer supported.

• For information about software support lifecycle, see: IBM Lifecycle Support for z/OS (www.ibm.com/software/support/systemsz/lifecycle)
• For information about currently-supported IBM hardware, contact your IBM representative.

Programming interface information

This document primarily documents information that is NOT intended to be used as Programming Interfaces of EIM.

This document also documents intended Programming Interfaces that allow the customer to write programs to obtain the services of EIM. This information is identified where it occurs, either by an introductory statement to a chapter or section or by the following marking:

[Programming Interface Information] The EIM APIs are a programming Interface. They are intended for customers to use in customer-written programs. [End Programming Interface Information]
